## 4.1 Negligible function

What is exactly a negligible function? Below here there is a possible interpretation of this notion:

“In real life, we can just consider adversaries with limited computational power; even if every non-perfectly secure authentication scheme can resist to unbounded computational power, the true unbounded computational power doesn’t exist at all. So, it’s reasonable to consider just bounded adversaries.

So consider a scheme  $\Pi$  where the only attack against it is brute-force attack. We consider  $\Pi$  to be secure if it cannot be broken by a brute-force attack in polynomial time.

The idea of **negligible probability** encompasses this exact notion. In  $\Pi$ , let’s say that we have a polynomial-bounded adversary. Brute force attack is not an option.

But instead of brute force, the adversary can try (a polynomial number of) random values and hope to guess the right one. In this case, we define security using negligible functions: The probability of success has to be smaller than the reciprocal of any polynomial function.

And this makes a lot of sense: if the success probability for an individual guess is a reciprocal of a polynomial function, then the adversary can try a polynomial amount of guesses and succeed with high probability. If the overall success rate is  $\frac{1}{poly(\lambda)}$  then we consider this attempt a feasible attack to the scheme, which makes the latter insecure.

So, we require that the success probability must be less than the reciprocal of every polynomial function. This way, even if the adversary tries  $poly(\lambda)$  guesses, it will not be significant since it will only have tried:  $\frac{poly(\lambda)}{superpoly(\lambda)} \cdot 1$

As  $\lambda$  grows, the denominator grows far faster than the numerator and the success probability will not be significant.<sup>2</sup>”

---

<sup>1</sup>If we design a function hard for  $superpoly(\lambda)$  possible attempts and the attacker completed  $poly(\lambda)$  attempts, he has just  $\mathcal{P}[\frac{poly(\lambda)}{superpoly(\lambda)}]$  of finding the key to break the scheme

<sup>2</sup><https://crypto.stackexchange.com/questions/5832/what-exactly-is-a-negligible-and-non-negligible-function>

**Definition**

Let  $\nu : \mathbb{N} \rightarrow [0, 1]$  be a function. Then it is deemed **negligible** iff:

$$\forall p(\lambda) \in \text{poly}(\lambda) \implies \nu(\lambda) \in o\left(\frac{1}{p(\lambda)}\right)$$

**Exercise 1.** Let  $p(\lambda), p'(\lambda) \in \text{poly}(\lambda)$  and  $\nu(\lambda), \nu'(\lambda) \in \text{negl}(\lambda)$ . Then prove the following:

1.  $p(\lambda) \cdot p'(\lambda) \in \text{poly}(\lambda)$
2.  $\nu(\lambda) + \nu'(\lambda) \in \text{negl}(\lambda)$

**Solution 1** (1.1). T0D0 1: Questa soluzione usa disuguaglianze deboli; per essere negligibile una funzione dev'essere strettamente minore di un polinomiale inverso. Da approfondire

We need to show that for any  $c \in \mathbb{N}$ , then there is  $n_0$  such that  $\forall n > n_0 \implies h(n) \leq n^{-c}$ .

So, consider an arbitrary  $c \in \mathbb{N}$ . Then, since  $c + 1 \in \mathbb{N}$ , and both  $f$  and  $g$  are negligible, there exists  $n_f$  and  $n_g$  such that:

$$\begin{aligned} \forall n \geq n_f &\implies f(n) \leq n^{-(c+1)} \\ \forall n \geq n_g &\implies g(n) \leq n^{-(c+1)} \end{aligned}$$

Fix  $n_0 = \max(n_f, n_g)$ . Then, since  $n \geq n_0 \geq 2$ ,  $\forall n \geq n_0$  we have:

$$\begin{aligned} h(n) &= f(n) + g(n) \\ &\leq n^{-(c+1)} + n^{-(c+1)} \\ &= 2n^{-(c+1)} \\ &\leq n^{-c} \end{aligned}$$

Thus we conclude  $h(n)$  is negligible.

## 4.2 ONE WAY FUNCTION

A OWF is a function "hard to invert".

**Definition 1.** The function

$$f : \{0, 1\}^{n(\lambda)} \rightarrow \{0, 1\}^{n(\lambda)} \quad (4.1)$$

is a OWF, if

$$\forall PPTA \exists \nu(\lambda) \in \text{negl}(\lambda) \quad (4.2)$$

such that

$$\mathcal{P}[GAME_{f,A}^{owf}(\lambda) = 1] \leq \nu(\lambda) \quad (4.3)$$

◇

**Exercise 2.** Show that  $\exists A$  inefficient and wins with probability 1, and exists  $A$  efficient winning with probability  $2^{-n}$ .

Figure 4.1: Game for OWF

### 4.3 One way puzzle

A one-way function can be thought as a function which is very efficient in generating puzzles, and these puzzles are very hard to solve. Furthermore, the person generating the puzzle knows a solution to it and can efficiently verify the validity of (possible other) solutions to the puzzle.

For a give couple  $(P_{GEN}, P_{VER})$  of a puzzle generator and a puzzle verifier, we have :

Figure 4.2: One way puzzle scheme

So, we can say that One-way Puzzle is a problem in NP(because solutions are easy to verify ), while not in P(because a solution is hard to provide).

### 4.4 Impagliazzo Worlds

Suppose to have Gauss, a genius child, and his professor. The professor gives to Gauss some mathematical problems, and Gauss wants to solve them all. Immagine now that, if using one-way functions, the problem is  $f(x)$  , and the solution to the problem is  $x$ .

According to Impagliazzo, we live in one of these possible worlds:

- Algorithmica , where  $P=NP$  , and all the problems easy to verify are also easy to solve, (so the Professor can try as hard as possible to break the

scheme, but without success, since Gauss will solve them all using the verification procedure to compute the solution);

- Heuristica, NP problems are hard to solve in the worst case but easy on average, (so the professor, with some effort, can create a game difficult enough, but Gauss will solve it anyway; here there are some problems that the professor cannot find a solution to);
- Pessiland, NP problems are hard on average but no one-way functions exist
- Minicrypt, OWF exist but we don't have public-key cryptography,
- Cryptomania, public-key cryptography is possible, i.e. two parties can exchange secret messages over open channels.

## 4.5 Computational Indistinguishability

Distribution ensemble  $X = X_{\lambda \in \mathbb{N}}$  and  $Y = Y_{\lambda \in \mathbb{N}}$  are a sequence of distributions.

**Definition 2.**  $X$  and  $Y$  are computationally **indistinguishable** ( $X \approx_c Y$ ) if  $\forall PPT.D, \exists \nu(\lambda) \in \text{negl}(\lambda)$  such that

$$|\mathcal{P}[D(X_\lambda) = 1] - \mathcal{P}[D(Y_\lambda) = 1]| \leq \nu(\lambda) \quad (4.4)$$

◇

Suppose we have this mental game: a Distinguisher  $D$  receives the value  $z$ . This value has been chosen by me, the Challenger, among  $X_\lambda$  and  $Y_\lambda$ , and the Distinguisher has to *distinguish* which was the source of  $z$ . What does this formula mean?

This formula means that, fixed 1 as one of the sources, the *probability* that  $D$  says "1!" when I pick  $z$  from  $X_\lambda$  is **not so far** from the *probability* that  $D$  says "1!" when I pick  $z$  from  $Y_\lambda$ .

So, this means that, when this property is verified by two random variables, there isn't too much *difference* between the two variables in terms of exposed information (reachable by  $D$ ), otherwise the distance between the two probabilities should be much more than a *negligible* quantity.

What's the deep meaning of this formula? This is something to do.

**Lemma 1.** If  $X \approx_c Y$  then  $\forall PPT.f$  we have  $f(x) \approx_c f(y)$ . ◇

*by contradiction.* We want to show that  $f(x) \approx_c f(y)$ . So, let's suppose this property is not true.

Assume  $\exists PPT.f, D'$  and some  $p'(\lambda) \in \text{poly}\lambda$  such that

$$|\mathcal{P}[D'(f(x)) = 1] - \mathcal{P}[D'(f(y)) = 1]| > \frac{1}{p'(\lambda)} \quad (4.5)$$

So  $D'$  which can distinguish  $f(x)$  and  $f(y)$ :

. But, if this kind of distinguisher would exist, we could use this distinguisher to distinguish  $X$  and  $Y$ .

Figure 4.3: Distinguisher of  $f(x) \approx_c f(y)$

We can build something like this:

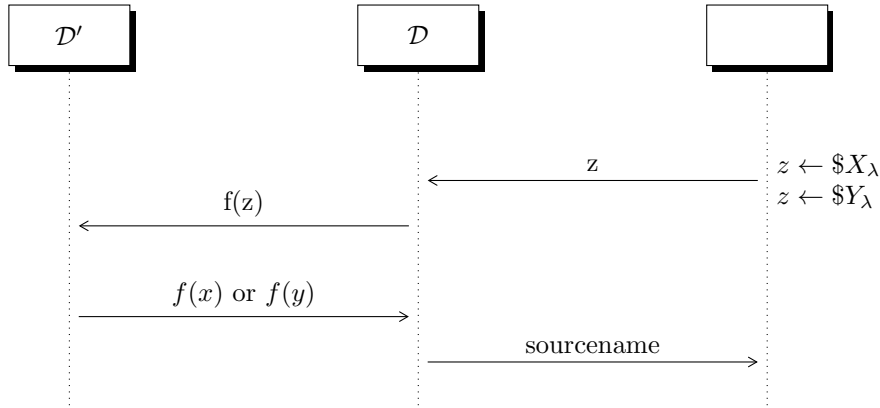

Figure 4.4: The reduction done

So, if  $\mathcal{D}'$  could distinguish between  $f(x)$  and  $f(y)$ , this means that its output can be used to distinguish also the main problem in polynomial time (since  $\mathcal{D}'$  is a PPT), the distinction about  $X_\lambda$  and  $Y_\lambda$ .

□

## 4.6 Pseudorandom Generator (PRG)

A deterministic function  $G : \{0, 1\}^\lambda \rightarrow \{0, 1\}^{\lambda+l(\lambda)}$  is a PRG if :

- $G$  is polynomial time, so it runs in polynomial time
- $|G(s)| = \lambda + l(\lambda)$
- $G(U_\lambda) \approx_c U_{\lambda+l(\lambda)}$

So, if we take  $s \leftarrow \$U_\lambda$ , the output of  $G$  will be indistinguishable from a random draw from  $U_\lambda$ .

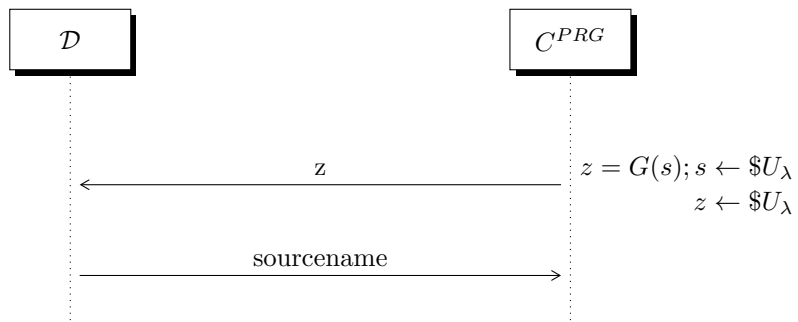

Figure 4.5: Pseudorandom generator game

# Lesson 5

## 4.7 Stretching a PRG

**Theorem 3.** *If there exists a PRG  $G : \{0, 1\}^\lambda \rightarrow \{0, 1\}^{\lambda+1}$ , then  $\forall l(\lambda) \in \text{poly } \lambda$  there exists a PRG with stretch  $G : \{0, 1\}^\lambda \rightarrow \{0, 1\}^{\lambda+l(\lambda)}$*   $\diamond$

*Proof.* Consider this algorithm/construction:

1. Let  $s_0 \leftarrow \{0, 1\}^\lambda$
2.  $\forall i \in [l]$ , let  $(s_i, b_i) = G(s_{i-1})$
3. Output  $b_1, b_2, \dots, b_l, s_l$ , so the output is a string of bit  $\lambda + l(\lambda)$  long

Following this algorithm, we should obtain the following representation of  $G^l$ :

Figure 4.6: graphical representation of  $G^l$

To show that the theorem is valid, we will use a proof by contradiction: trying to show that  $G^\lambda$  is not a PRG, we will see that  $G$  should be not a PRG, contradicting the theorem.

Different sources give different interpretations of this proof. As of now, the following one is an outline of the proof that seems to make sense, more or less. This proof should, however, be marked as TO BE REVIEWED.

The step points of this proof are:

1. Prove that  $H_\lambda^i \approx_c H_\lambda^{i+1}$ ,  $\forall i \in [0, l]$ ;
2. Prove the **hybrid argument**: if  $X \approx_c Y$  and  $Y \approx_c Z$ , then  $X \approx_c Z$ ;
3. With the hybrid argument, prove that:

$$G^l(U_\lambda) = H_\lambda^0 \approx_c H_\lambda^1 \approx_c \dots \approx_c H_\lambda^l = U_{l+\lambda}$$

4. Now, since  $H_\lambda^i \approx_c U_{\lambda+l}$ , it's possible to use the contradiction, masked as a proof by reduction.

To prove point 1, define the following names:

- $H_\lambda^0 := G^l(U_\lambda)$
- $H_\lambda^i := \begin{cases} b_1, \dots, b_i \leftarrow \mathcal{S}\{0, 1\} \\ s_i \leftarrow \{0, 1\}^\lambda \\ (b_{i+1}, \dots, b_l, s_l) := G^{l-i}(s_i) \end{cases}$
- $H_\lambda^l := U_{\lambda+l}$

So  $H^i$  is just taking in input the number  $x_i$ , executing  $l - i$  times  $G$  and obtaining a sequence of bytes.

Now, just have a look at those figures:

Figure 4.7:  $H_\lambda^i$

Figure 4.8:  $H_\lambda^{i+1}$

$H^i$  and  $H^{i+1}$  differ just for the input given to the  $(i + 1)$ -th step of the algorithm:

- in  $H^i$ , this input is pseudorandom;
- in  $H^{i+1}$ , this input comes from  $U_\lambda$

Now consider a function <sup>3</sup>

$$f_i(s_{i+1}, b_{i+1}) = \begin{cases} b_1, \dots, b_i \leftarrow \mathcal{S}\{0, 1\} \\ \forall j \in \{i + 2, l\}, G(s_{j-1}) = \{s_j, b_j\} \\ \text{output} := \{b_1, \dots, b_l, s_l\} \end{cases}$$

Given this function, it's possible to notice that:

- $f_i(U_{\lambda+1})$  has the same distribution of  $H^{i+l}$
- $f_i(G(U_\lambda))$  has the same distribution of  $H^i$

<sup>3</sup>Why do we define  $f_i$ ? Such that we know that the first input given to  $G$  in the function will be considered  $s_{i+1}$ .

Given 1, since by definition

$$G(U_\lambda) \approx_c U_{\lambda+1}$$

then also

$$f_i(G(U_\lambda)) \approx_c f_i(U_{\lambda+1})$$

and so  $H^i \approx_c H^{i+1}$ .

Now, to prove 2 :

$$X \approx_c Z \Rightarrow \quad (4.6)$$

$$|\mathcal{P}[D(X) = 1] - \mathcal{P}[D(Z) = 1]| \leq \nu(\lambda) \quad (4.7)$$

$$|\mathcal{P}[D(X) = 1] - \mathcal{P}[D(Y) = 1] + \mathcal{P}[D(Y) = 1] - \mathcal{P}[D(Z) = 1]| \leq \quad (4.8)$$

$$\leq |\mathcal{P}[D(X) = 1] - \mathcal{P}[D(Y) = 1]| + |\mathcal{P}[D(Y) = 1] - \mathcal{P}[D(Z) = 1]| \quad (4.9)$$

$$\leq \nu(\lambda) + \nu(\lambda) = \nu(\lambda) \quad (4.10)$$

Now, to prove 3, it's just needed to notice that

$$H_\lambda^i \approx_c \dots \approx_c H_\lambda^{l-1} \approx_c H_\lambda^l \approx_c U_{l+\lambda} \quad (4.11)$$

for what's valid in point 1 and point 2.

Now, use a contraddiction.

Suppose  $G^l$  is not a PRG  $\Rightarrow$

$$\begin{aligned} G^l(U_\lambda) \not\approx_c U_{\lambda+l} = H^l \not\approx_c H^0 \Rightarrow \\ \exists i \in [0, l], \exists PPT.D', p'(\lambda) \in \text{poly}\lambda \\ |\mathcal{P}[D'(H^i) = 1] - \mathcal{P}[D'(H^{i+l}) = 1]| \geq \frac{1}{p'(\lambda)} \end{aligned}$$

This formula comes from observing that, since  $H^l \not\approx_c H^0$ , there must be a point in the chain  $H^0 \approx_c H^1 \approx_c \dots \approx_c H^l$  where  $H^i \not\approx_c H^{i+1}$ ; so there exist  $D'$  capable of distinguish them.

Figure 4.9: Distinguisher for  $H^i$  and  $H^{i+1}$

If such a distinguisher exists, it can be also used to distinguish the output of function  $G$  from  $U_{\lambda+1}$ :

Figure 4.10: If  $(s_{i+1}, b_{i+1})$  comes from  $G(s^*)$ ,  $\mathcal{D}'$  finds  $H^i$ , otherwise it finds  $H^{i+1}$

So we have a contradiction, because we cannot distinguish a PRG, by definition.  $\square$

## 4.8 Hard-core predicate

Now, consider a typical one-way function  $f$ , s.t.  $f(x) = y$ .

**Question 1.** Which bits of the input  $x$  are hard to compute given  $y = f(x)$ ? Is it always true that, given  $f$  and  $f(x)$ , the first bit is hard to compute for every  $x$ ?

**Example 1.** Given an OWF  $f$ , then  $f'(x) = x[0] || f(x)$  is a OWF.

**Definition 1.** A polynomial time function  $h : \{0, 1\}^n \rightarrow \{0, 1\}$  is **hard core** for  $f : \{0, 1\}^n \rightarrow \{0, 1\}^n$  if

$$\forall PPT.A, \exists \nu(\lambda) \in \text{negl}(\lambda) \text{ such that} \\ \mathcal{P}[A(f(x)) = h(x) | x \leftarrow \$\{0, 1\}^n] \leq \nu(\lambda)$$

Figure 4.11: Hard-core function, game of definition 1

There is also an alternative definition:

**Definition 2.** A Polynomial Time function  $h : \{0,1\}^n \rightarrow \{0,1\}$  is hard-core for  $f$  if

$$(f(x), h(x)) \approx_c (f(x), b)$$

where  $x \leftarrow \{0,1\}^n$  and  $b \leftarrow \{0,1\}$ .

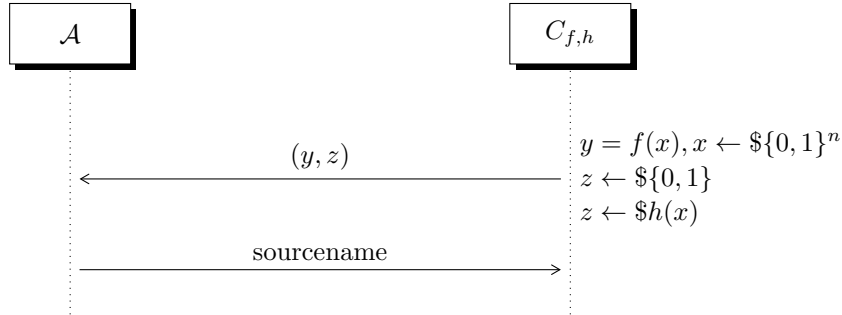

Figure 4.12: Hard-core function, game of definition 2

**Claim 1.** There is no *universal* hard-core function  $h$ .

A good  $h$  should be chosen for each different one-way function  $f$ .

Imagine  $h$  that works for all of the OWFs.

What about  $f'(x) = h(x) || f(x)$ ? If  $h$  is hardcore for  $f$  and  $f'$ , by the definition 1 of **hardcore function**  $h$  is applied on the same  $x$  and will return the same bit in  $\{0,1\}$  at every interrogation.

TO BE REVIEWED.

**Theorem 4** (Goldreich-Levin, '99). *Let  $f$  be an OWF and consider  $g(x, r) = (f(x), r)$  for  $r \in \{0,1\}^n$ . Then  $g$  is a OWF and*

$$h(x, r) = \langle x, r \rangle = \sum_{i\text{-th bit}} x_i r_i \text{ mod } 2 = \dots$$

=====

TO BE COMPLETED

=====

is hard core for  $g$ .

◇

**Exercise 5.** Prove that  $g$  is OWF if  $f$  is OWF. (by reduction)

## 4.9 One Way Permutation

$f : \{0, 1\}^n \rightarrow \{0, 1\}^n$  is an OWF and

$$\forall x, |x| = |f(x)| \wedge x \neq x' \Rightarrow f(x) \neq f(x')$$

**Corollary 1.** If  $f : \{0, 1\}^n \rightarrow \{0, 1\}^n$  is a OWP, then for  $g(), h()$  as in the GL theorem,

$$G(s) = (g(s), h(s))$$

is a PRG.

*Proof.* By GL, if  $f$  is an OWP, so is  $g$ . This means that if we want to invert  $g$ , since  $g$  depends on  $f$  we have to invert a OWP.

Moreover  $h$  is hardcore for  $g$ . Hence

$$G(U_{2n}) \equiv (g(U_{2n}), h(U_{2n})) \equiv \underbrace{(f(U_n), U_n, h(U_{2n}))}_{\text{definition 1 of hard core pred.}} \approx_c (f(U_n), U_n, U_1) \equiv U_{2n+1}$$

□

We are stretching just 1 bit, but we know we can stretch more than one.

# Lesson 6

## 4.10 Computationally secure encryption

**Question 2.** How to define the concept of **computationally secure encryption** ?

Find a task/scheme that is computationally hard for an attacker to break (supposing the attacker is  $\text{poly}\lambda$ , we want a scheme which requires an amount of time near ,as much as possible, to *superpoly*( $\lambda$ ) to be broken).

This scheme should have these properties:

- **one wayness** w.r.t. key (given  $c = \text{Enc}(k, m)$ , it should be hard to recover  $k$ )
- **one wayness** w.r.t. message (given  $c = \text{Enc}(k, m)$ , hard to obtain the message)
- **no information leakage** about the message

Consider the following experiment for  $\Pi = (\text{Enc}, \text{Dec})$ , named

$$GAME_{\Pi, \mathcal{A}}^{\text{ind}}(\lambda, b)$$

In the image  $b'$  means that if  $m_{b'} = m_b$  the adversary wins.

**Definition 3.** We say that  $\Pi$  is computationally **one time secure** if

$$Game_{\Pi, \mathcal{A}}^{ind}(\lambda, 0) \approx_c Game_{\Pi, \mathcal{A}}^{ind}(\lambda, 1)$$

or, alternatively  $\forall .PPT.\mathcal{A} \exists \nu(\lambda) \in \text{negl}(\lambda)$

$$|\mathcal{P}[Game_{\Pi, \mathcal{A}}^{ind}(\lambda, 0) = 1] - \mathcal{P}[Game_{\Pi, \mathcal{A}}^{ind}(\lambda, 1) = 1]| \leq \nu(\lambda)$$

4

◇

This last definition is compliant with the three properties before exposed, in particular:

if a scheme is **one time secure**  $\Rightarrow$  the scheme has each one of these 3 properties

- **compliance with point 1** : suppose point 1 is not valid, and  $k$  is not hard to discover for  $\mathcal{A}$ . But then  $\mathcal{A}$  is able to perfectly distinguish  $m$  and  $m_0$  with  $\mathcal{P}[1]$  every time, and so the scheme couldn't be one time secure;
- **compliance with point 2** : suppose point 2 is not valid, and then the encrypted message can be easily discovered by  $\mathcal{A}$ . But then , as before,  $\mathcal{A}$  can win every game with  $\mathcal{P}[1]$  , so the scheme couldn't be one time secure;
- **compliance with point 3** : suppose point 3 is not valid, and some information about  $m$  is leaked in  $c$ , for example the first bit of  $c$  is the same bit of  $m$  .  $\mathcal{A}$  could forge  $m_0 == m$  such that they have the same bits but just the first is different. When  $\mathcal{A}$  obtains  $c$ , he can look at the first bit and distinguish which was the message encrypted. Thus, the scheme wouldn't be one time secure. TO BE REVIEWED.

What is not **two time secure** ?

**Construction 1.** Let  $G : \{0, 1\}^\lambda \rightarrow \{0, 1\}^l$ . Consider the following schema  $\Pi_\oplus$ :

- $\mathcal{K} = \{0, 1\}^\lambda \Rightarrow k \leftarrow \mathcal{K}$
- $Enc(k, m) = G(k) \oplus m, m \in \{0, 1\}^l$
- $Dec(k, c) = c \oplus G(k) = m$

◇

This construction isn't 2-time secure. Assume the pair

$$(\bar{m}, \bar{c} = G(k) \oplus \bar{m})$$

is known. Now , given  $c = G(k) \oplus m$ , where  $c$  and  $m$  are unknown, we can force the schema and do the following

$$\bar{c} = G(k) \oplus m = c \oplus m \oplus \bar{m} \Rightarrow c \oplus \bar{c} = m \oplus \bar{m}$$

and obtain  $m$ .

**Theorem 6.** If  $G$  is a PRG, then  $\Pi_\oplus$  is computationally one-time secure ◇

Figure 4.13: Game for  $\Pi_{\oplus}$  schema ( $Game_{\Pi_{\oplus}, \mathcal{A}}$ )

*Proof.* We need to show that

$$Game_{\Pi_{\oplus}, \mathcal{A}}^{ind}(\lambda, 0) \approx_c Game_{\Pi_{\oplus}, \mathcal{A}}^{ind}(\lambda, 1)$$

So first consider the following **hybrid game** :

Figure 4.14: Hybrid game ( $\mathcal{HVB}_{\Pi_{\oplus}, \mathcal{A}}(\lambda, b)$ )

**Lemma 2.**  $\mathcal{HVB}_{\Pi_{\oplus}, \mathcal{A}}(\lambda, 0) \equiv \mathcal{HVB}_{\Pi_{\oplus}, \mathcal{A}}(\lambda, 1)$   $\diamond$

This is true because distribution of  $c$  doesn't depend on  $b \in \{0, 1\}$ .

**Lemma 3.**  $\forall b \in \{0, 1\}, \mathcal{HVB}_{\Pi_{\oplus}, \mathcal{A}}(\lambda, b) \approx_c Game_{\Pi, \mathcal{A}}^{ind}(\lambda, b)$   $\diamond$

*Proof.* Simple reduction to PRG, supposing that the statement isn't true.

This means that there exists  $\mathcal{A}'$  capable of distinguish  $c = m_b \oplus G(k)$  and  $c = m_b \oplus u$ .

We will prove this first with  $b = 0$  (the other case is the same).

---

<sup>4</sup> $Game^{ind}$  refers to the indistinguishability of the messages sent by the attacker during the game

If  $\mathcal{A}'$  could distinguish these two sources, then  $C^{prg}$  could be distinguished, but this is impossible.  $\square$

Now, for the two lemmas just seen, we have

$$Game_{\Pi, \mathcal{A}}^{ind}(\lambda, 0) \approx_c \mathcal{HYB}_{\Pi \oplus, \mathcal{A}}(\lambda, 0) \equiv \mathcal{HYB}_{\Pi \oplus, \mathcal{A}}(\lambda, 1) \approx_c Game_{\Pi, \mathcal{A}}^{ind}(\lambda, 1)$$

$\square$

## 4.11 Pseudorandom functions

A random function

$$R : \{0, 1\}^n \rightarrow \{0, 1\}^l$$

. is a function that takes in input  $x$  and :

- returns a new  $R(x) = y \leftarrow \$\{0, 1\}^l$  if  $x$  has never been saw before and records that value (so **two distinct inputs can collide** )
- returns the recorded  $R(x)$  otherwise

. We could generate these functions, but they occupy too much space: supposing all the possible outputs of  $R$  have been generated and stored in an array in memory, the occupied bits in memory are  $2^n l$ .

In particular, the family  $\mathcal{R} = \{R : \{0, 1\}^n \rightarrow \{0, 1\}^l\}$ , also indicated as  $\mathcal{R}(\lambda, n, l)$ , containing all the possible random functions has cardinality  $2^{2^n l}$ .

**Intuition:** a pseudo-random function is indistinguishable (computationally speaking) from a truly random one.

Call  $\mathcal{F} = \{F_k : \{0, 1\}^{n(\lambda)} \rightarrow \{0, 1\}^{l(\lambda)}\}_{k \in \{0, 1\}^\lambda}$  the family of pseudorandom functions with key  $k$ . To give a definition of pseudo-random function, consider the following games:

Figure 4.15:  $Real_{\mathcal{F}, \mathcal{A}}(\lambda)$  vs  $Rand_{\mathcal{R}, \mathcal{A}}(\lambda)$

where  $b' \in \{0, 1\}$  is a convention and 1 is assigned to *Real* or *Rand*; so in this game the adversary **recognizes** which machine he is talking with.

**Definition 4.**  $\mathcal{F}$  is a PRF family if

$$Real_{\mathcal{F}, \mathcal{A}}(\lambda) \approx_c Rand_{\mathcal{R}, \mathcal{A}}(\lambda)$$

◇

**Exercise 7.** Show that no PRG is secure against **unbounded attackers**.

**Exercise 8.** Show the same (as above) for PRF.

#### 4.11.1 GGM Tree

**Construction 2.** Let  $G : \{0, 1\}^\lambda \rightarrow \{0, 1\}^{2\lambda}$  be a PRG and let us write

$$G(k) = (G_0(k), G_1(k))$$

Now consider this tree, called **GGM tree**, which describes the use of  $G(k)$ :

GGM TREE IMAGE

Build  $\mathcal{F} = \{F_k : \{0, 1\}^n \rightarrow \{0, 1\}^\lambda\}$  such that

$$F_k(x) = G_{x_n}(G_{x_{n-1}} \dots G_{x_2}(G_{x_1}(k)))$$

◇

For example, in the tree with height  $n = 3$ , for  $x = 001$  we have  $F_k(001)$ , which is  $G_0(G_0(G_1(k)))$ .

# Lesson 7

**WARNING : I was absent**

**Theorem 9.** *If  $G$  is a PRG, then  $F_{GGM}$  is a PRF.*  $\diamond$

(this definition should mean implicitly that the  $k$  key has been chosen by the challenger before the proof starts)

*Proof.* TO BE REVIEWED. Now use the induction on the height  $n$  of the GGM tree for  $\nu(\lambda) \in \text{poly}\lambda$ .

**Base Case**  $\Rightarrow n = 1$  follows by security of PRG  $G$  function, because

$$(F_k(0), F_k(1)) = (G_0(k), G_1(k)) \approx_c U_{2\lambda}$$

This means that, chosen  $k$ , the two values returned by  $F$  are indistinguishable from 2 values taken at random and inserted in the truth table of a possible random function. Since these values are indistinguishables, the source functions are indistinguishables and  $F_k$  is pseudorandom.

Now, for the **Inductive step** :

**Lemma 4.** *Let  $F' : \{0, 1\}^{n-1} \rightarrow \{0, 1\}^\lambda$  be a PRF. Now define  $F_k(x, y) = G_x(F'_k(y))$  where  $F_k : \{0, 1\}^n \rightarrow \{0, 1\}^\lambda$ . If  $\{F'_k\}$  is a PRF so is  $\{F_k\}$ .*  $\diamond$

Consider the following images:

Figure 4.16:  $\mathcal{HYB}_{\mathcal{F}, \mathcal{A}}^0(\lambda)$

Figure 4.17:  $\mathcal{HYB}_{\mathcal{R}', G, \mathcal{A}}^1(\lambda)$

Figure 4.18:  $\mathcal{HYB}_{\mathcal{R}, \mathcal{A}}^2(\lambda)$

**Lemma 5.**  $\mathcal{HYB}^0 \approx_c \mathcal{HYB}^1 \approx_c \mathcal{HYB}^2$ . ◇

**Claim 2.**  $\mathcal{HYB}^0 \approx_c \mathcal{HYB}^1$

Assume  $\exists.PPT.D_{01}$  that can distinguish  $F_k$  and  $H$ ; then there may exist a distinguisher  $D$  as in the image which breaks the assumption made by inductive step.

**Claim 3.**  $\mathcal{HYB}^1 \approx_c \mathcal{HYB}^2$

For this proof we use the following simple lemma.

**Lemma 1.** If  $G : \{0, 1\}^\lambda \rightarrow \{0, 1\}^{2\lambda}$  is a PRG, then for any  $t(\lambda) \in \text{poly}\lambda$

$$(G(k_1), \dots, G(k_t)) \approx_c (U_{2\lambda}, \dots, U_{2\lambda})$$

for  $k_1, \dots, k_t \leftarrow \$U_\lambda$

Assume that it exists a distinguisher  $D_{1,2}$  which is capable of distinguish  $H(x, y)$  and  $R(x, y)$ .

...TO REVIEW, NOT UNDERSTOOD AT ALL ...

□

## 4.12 CPA SECURITY

Suppose  $G$  is a PRG.

Given  $\text{Enc}(k, m) = G(k) \oplus m$ , and a known  $(\bar{m}, \bar{c})$  where  $c = G(k) \oplus m$ , then this function is not 2 time secure, since  $c \oplus \bar{c} = m \oplus \bar{m}$ , easy to invert. (??? some glue arguments missing ???)

Figure 4.19:  $\text{Game}_{\Pi, \mathcal{A}}^{cpa}(\lambda, b)$

The adversary wins if finds which  $m_b^*$  message was previously encrypted. For sure  $m_i$  can be equal to  $m_0$  or  $m_1$ .

The two cyclic requests, before and after the starred messages, can be arbitrarily long (also 0, there is no constraint).

**Definition 5.** A scheme is CPA-secure if  $\text{Game}_{\Pi, \mathcal{A}}^{cpa}(\lambda, 0) \approx_c \text{Game}_{\Pi, \mathcal{A}}^{cpa}(\lambda, 1)$  ◇

**Observation 1.** No deterministic scheme can achieve CPA security. ◇

This is because the Adversary is not limited in what he can ask to the Challenger: if he asks  $m_0$  and  $m_1$  before sending the starred messages, he will know

in advance the encrypted form of the messages, and he will be able to distinguish with  $\mathcal{P}[\text{Game}^{cpa}] = 1$  the two games.

So, a way to obtain a CPA-secure encryption scheme consists of returning different cyphertexts for the same message, and we can build a scheme which tries to generate this kind of output using PRFs.

Consider the following SKE scheme  $\Pi$ .  
Let  $\mathcal{F} = \{F_k : \{0, 1\}^n \rightarrow \{0, 1\}^l\}$  be a PRF:

- $k \leftarrow \$U_\lambda$
- $\text{Enc}(k, m)$ , picking a random  $r \leftarrow \$\{0, 1\}^n$  with an output of  $c = (c_1, c_2) = (r, F_k(r) \oplus m) \leftarrow \$\{0, 1\}^{n+l}$
- $\text{Dec}(k, (c_1, c_2)) = F_k(c_1) \oplus c_2$

. In this scheme, the only secret thing is  $k$ , which gives a *flavour* to the random function; Adversary can see  $c = (r, F_k(r) \oplus m)$ , so he can see  $r$ .

**Theorem 10.** *If  $\mathcal{F}$  is a family of PRF functions, then  $\Pi$  is CPA-secure*  $\diamond$

To prove this, we have to prove that  $\text{Game}_{\Pi, \mathcal{A}}^{cpa}(\lambda, 0) \approx_c \text{Game}_{\Pi, \mathcal{A}}^{cpa}(\lambda, 1)$ .

*Proof.* Consider hybrid arguments

$$\mathcal{HYB}_0 \equiv \text{Game}_{\Pi, \mathcal{A}}^{cpa}(\lambda, 0)$$

and

$$\mathcal{HYB}_1$$

, like  $\mathcal{HYB}_0$  but with another distribution of  $\text{Enc}(k, m_b)$ :

- picking  $r \leftarrow \$\{0, 1\}^n$
- $R \leftarrow \$\mathcal{R}(\lambda, n, l)$
- output obtained is  $(r, R(r) \oplus m_b)$

and

$$\mathcal{HYB}_2(\lambda, b)$$

which simply outputs  $(r_1, r_2) \leftarrow \$U_{n+l}$ .

**Lemma 6.**  $\mathcal{HYB}_0 \approx_c \mathcal{HYB}_1$  for each  $b \in \{0, 1\}$   $\diamond$

*Proof.* Suppose these two hybrids are distinguishable; but then we can use the related distinguisher to break the starting assumption saying  $\mathcal{F}$  is a PRF.

Since they are two similar games (but just for the encryption function), we can use the CPA game for this reduction.

Fix  $b = 0$  and build the following

After the last message,  $\mathcal{D}_{01}$  will reply with a  $b' \in \{0, 1\}$  which expresses which one of the encryption functions has been used; since this result can be used for solving the PRF game, the starting assumption fails and the lemma is proven.  $\square$

**Lemma 7.**  $\mathcal{HYB}_1 \approx_c \mathcal{HYB}_2$   $\diamond$

*Proof.* Even if the output of the first hybrid is  $(r_i, R(r_i) \oplus m_b)$ , the distribution of the second member of this couple doesn't depend on  $m_b$ , hence we can assume that  $R(r_i) \oplus m_b \equiv R(r_i)$ .

The difference between  $\mathcal{HYB}_1$  and  $\mathcal{HYB}_2$  comes if we play the game once more and we pick up the same  $c_1$  of the first game: while in  $\mathcal{HYB}_2$   $r_2$  is independent from  $r_1$  and will be different from the previous  $r'_2$  with probability near to 1, in  $\mathcal{HYB}_1$  (if  $r_i$  is the same of the previous game)  $R(r_i)$  will be the same of the previous game (because  $R()$  is a random function).

Anyway, we can show that this "collision" happens with very low probability.

Call **REPEAT** this event of collision of  $r_i$  between 2 consecutive games. To show the statement of the lemma, it suffices to show that  $P[\text{REPEAT}] \in \text{negl}(\lambda)$ , therefore the two distributions are indistinguishable (or distinguishable with a negligible probability).

In fact, if I make  $q$  queries to  $\mathcal{HYB}_1$ ,

$$\begin{aligned}
P[REPEAT] &= P[\exists i, j \in q \text{ such that } r_i = r_j] \leq \\
&\leq \sum_{i, j \wedge i \neq j} \mathcal{P}[r_i = r_j] = Col(U_n) = \\
&= \sum_{i \wedge j, i \neq j} \sum_{e \in \{0,1\}^n} \mathcal{P}[r_1 = r_2 = e] = \\
&= \sum_{i \wedge j, i \neq j} \sum_{e \in \{0,1\}^n} \mathcal{P}[r = e]^2 = \\
&= \binom{q}{2} 2^n \frac{1}{2^{2n}} = \\
&= \binom{q}{2} 2^{-n} \leq \\
&\leq q^2 2^{-n} \in \text{negl}(\lambda)
\end{aligned}$$

□

Since  $\mathcal{HYB}_0 \equiv Game(\lambda, 0)$  but the same proofs can be made for  $Game(\lambda, 1)$ ,  
 $Game(\lambda, 0) \equiv \mathcal{HYB}_0(Game(\lambda, 0)) \approx_c \mathcal{HYB}_2 \approx_c \mathcal{HYB}'_0(Game(\lambda, 1)) \equiv Game(\lambda, 1)$

□

# Lesson 8

## 4.13 Domain extension

How can we encrypt long messages, say  $m = (m_1, m_2, \dots, m_t)$  where for  $i \in [t], m_i \in \{0, 1\}^n$ ?

Mode of operation: let's build  $P_k$ , a blockcypher.

### 4.13.1 Electronic CodeBook (ECB)

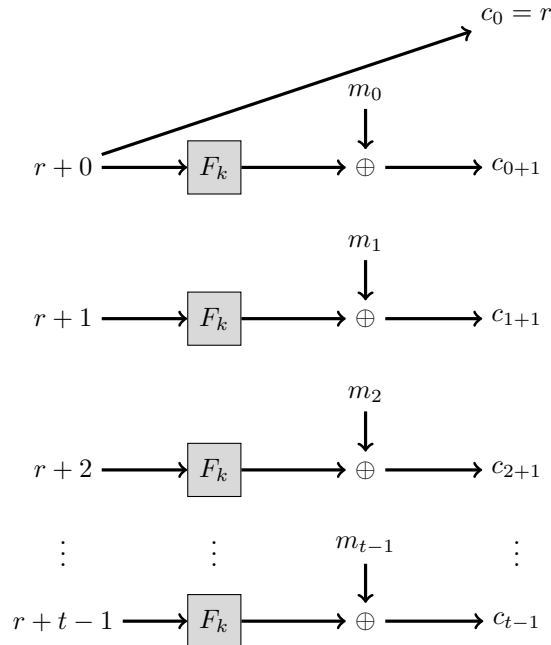

(In notes, this name is associated with CTR-mode, or **counter mode**, but why?)

The principle is that I have many blocks of information and I encrypt all of them individually (maybe in parallel):

$$c_i = P_k(m_i) \forall i \in [t]$$

and outputs  $c_1, c_2, \dots, c_t$ .

If I encrypt the same message, I obtain the same cyphertext. So it's not CPA-secure as the encryption function is **deterministic**.

In the image, each message is long exactly **n bits**, and

$$r \leftarrow \{0, 1\}^n$$

so the sums made over  $r$  are done in **mod**  $2^n$ , since  $r$  can be a number in the range  $[0, 2^n - 1]$ .

This is also called streamcipher, cause as input flows ECB produces the ciphertext. How to decrypt this schema? Since I know  $r_i$ , if I compute  $F_k(r_i)$  I can use the  $\oplus$ -operation to calculate the message.

#### 4.13.2 Cipher block chaining (CBC)

=====

CBC IMAGE =====

=====

The schema to cipher here is

$$\forall i \in [1, t] c_i = P_k(C_{i-1} \oplus m_i)$$

How to decipher?

$$P_k^{-1}(i) = c_{i-1} \oplus m_i$$

so  $m_i = P_k^{-1}(c_i) \oplus c_{i-1}$ .

**Theorem 11.** Assume  $\mathcal{F}$  ( $F_k$  in the image above is part of this family) is a PRF, then CTR-mode yields a CPA-secure SKE for variable length messages.

◇

Variable length messages means that every message

$$m = (m_1, \dots, m_t)$$

has  $t$  subsets, and  $t$  can change from message  $m$  to another message  $m' = (m'_1, \dots, m'_{t'})$ . Consider the following hybrids:

Figure 4.20:  $\text{Game}_{CTR,A}^{cpa}(\lambda, b)$

Figure 4.21:  $\mathcal{HB}_1(\lambda, b)$

Figure 4.22:  $\mathcal{HVB}_2(\lambda, b)$

Now we want to show that  $\text{Game}_{\Pi, \lambda}^{cpa}(\lambda, 0) \approx_c \text{Game}_{\Pi, \lambda}^{cpa}(\lambda, 1)$

*Proof.*

**Exercise 12.**

**Lemma 8.** *Show that  $\text{Game}_{\Pi, \lambda}^{cpa}(\lambda, b) \approx_c \mathcal{HVB}_1(\lambda, b), \forall b \in \{0, 1\}$*   $\diamond$

(Since this  $\text{Game}(\lambda, b)$  is a CPA scheme and the second one is very similar, we can use a distinguisher which plays the CPA game; since this is a lemma, our precondition to "break" during the reduction is the precondition contained in the theorem statement)

**Lemma 9.**  $\mathcal{HVB}_1(\lambda, b) \approx_c \mathcal{HVB}_2(\lambda), \forall b \in \{0, 1\}$   $\diamond$

The two hybrids are identical but for the encryption function, which is completely random in the second one while the first one uses a random function.

Since  $R(r + i) \oplus m_i \approx R(r + i)$  (because  $m_i$  doesn't affect the distribution of the result at all), if  $R(r^*)$  behaves like a true random extractor, the two hybrids are indistinguishable.

Now, if I examine a simple query and the consecutive challenge query  $(q, q^*)$  in a game in  $\mathcal{HVB}_2$ , the responses will be chosen at random with very low probability of being the same; but in a game in  $\mathcal{HVB}_1$ , the problem comes if the challenger creates an  $r^* + j'$  for  $q^*$  which overlaps some chosen  $r_i + j$  previously chosen for  $q$ .

This is bad, because  $R(r_i + j) = R(r^* + j')$  since  $R$  is a random function, and the probability of outputting the same response ciphertext will be much higher in  $\mathcal{HVB}_1$ .

It's possible to show that these collisions happen very few times (with **negligible** probability) in  $\mathcal{HVB}_1$  and that the two hybrids are distinct and distinguishable for a negligible factor.

*Proof.* Let :

- $q = \#$  of encryption queries
- $t_i = \#$  of blocks for the  $i$ -th query
- $t^* = \#$  of blocks for challenge

and let the function  $R$  run: we will have  $R(r^*), \dots, R(r^* + t^* - 1)$  and  $R(r_i), \dots, R(r_i + t_i - 1)$  sequences of random function outputs.

**Definition 6. OVERLAP event:**  $\exists i, j, j', r_i + j = r^* + j'$  (here  $j \leq t_i$  and  $j' \leq t^*$ ), for some query  $q_i$ .  $\diamond$

If **OVERLAP** does not happen, the sequence  $(R(r^*), \dots, R(r^* + t^* - 1))$  is made of **uniform** and **independent** values. Thus  $\mathcal{HYB}_1(b)$  is identical to  $\mathcal{HYB}_2(b)$  for all  $b \in \{0, 1\}$ .

Now it suffices to show that  $\mathcal{P}[\text{OVERLAP}] \in \text{negl}(\lambda)$ .

For simplicity, assume  $q = (\text{length of each query})$  and also  $t_i = t^* = q$ . Let  $\text{OVERLAP}_i$  be the event that the  $i$ -th query  $r_i, \dots, r_i + q - 1$  partially or totally overlaps the challenge sequence  $r^*, \dots, r^* + q - 1$ .

Fix some  $r^*$ .

One can see that  $\text{OVERLAP}_i$  happens if

$$r^* - q + 1 \leq r_i \leq r^* + q - 1$$

, which means that  $r_i$  should be chosen *at least* in a way that :

- the sequence  $r^*, \dots, r^* + q - 1$  comes before the sequence  $r_i, \dots, r_i + q - 1$ , and they overlap just for the last element  $r^* + q - 1 = r_i$  or
- the sequence  $r_i, \dots, r_i + q - 1$  comes before the sequence the sequence  $r^*, \dots, r^* + q - 1$ , and they overlap just for the last element  $r_i + q - 1 = r^*$

So now

$$\mathcal{P}[\text{OVERLAP}_i] = \frac{(r^* + q - 1) - (r^* - q + 1) + 1}{2^n} = \frac{2q - 1}{2^n}$$

It is obvious that, for definition of **OVERLAP**,

$$\mathcal{P}[\text{OVERLAP}] \leq \sum_{i=1}^q \mathcal{P}[\text{OVERLAP}_i] \leq 2 \frac{q^2}{2^n} \in \text{negl}(\lambda)$$

□

Since  $\mathcal{HYB}_1 \approx_c \mathcal{HYB}_2$  and  $\mathcal{HYB}_1 \equiv \text{Game}(b)$  with  $b$  equal to 0 and 1 respectively, we can state that

$$\text{Game}(0) \approx_c \mathcal{HYB}_2 \approx_c \text{Game}(1)$$

□

# Lesson 9

## 4.14 Message Authentication and UFCMA-security

First, remember the  $Tag()$  function and how a MAC works. Now  $Tag()$  is defined using a key  $k$ , and we call it  $Tag_k()$ .

In particular we are looking for a cool property of a message authentication protocol, called **universal unforgeability against chosen-message attacks**, which prevents the attacker from generating a valid couple  $(m^*, \phi^*)$  after some queries containing messages and receiving the related tags.

This property is defined through a game called

$$Game_{\Pi, \mathcal{A}}^{ufcma}(\lambda)$$

and played in the following manner:

Figure 4.23:  $Game_{\Pi, \mathcal{A}}^{ufcma}(\lambda)$

with  $m^*$  which must be a fresh new message never used before and with the Adversary  $\mathcal{A}$  which doesn't know the key  $k$  used in the tag.

**Definition 7.**  $\Pi$  is **ufcma-secure** if  $\forall .PPT.\mathcal{A}$

$$\mathcal{P}[Game_{\Pi, \mathcal{A}}^{ufcma}(\lambda) = 1] \in \text{negl}(\lambda)$$

◇

Now consider the following theorem:

**Theorem 13.** Let  $\mathcal{F} = \{F_k : \{0, 1\}^n \rightarrow \{0, 1\}^l\}_{k \in \{0, 1\}^\lambda}$  be a PRF family. Then  $\Pi$  which uses  $\text{Tag}_k() = F_k()$  is a UFCMA-secure MAC with  $n$ -bit domain.  $\diamond$

We show that the scheme which uses a PRF is indistinguishable from a scheme which uses a random function, and that a MAC scheme which uses a random function is breakable by an efficient attacker in negligible time.

*Proof.* Consider the two following hybrids:

Figure 4.24:  $\text{Game}_{\mathcal{F}, \mathcal{A}}^{ufcma}(\lambda)$

Figure 4.25:  $\mathcal{HYB}_{\mathcal{B}}^{ufcma}(\lambda)$

**Lemma 10.**  $\text{Game}_{\mathcal{F}, \mathcal{A}}^{ufcma}(\lambda) \approx_c \mathcal{HYB}_1^{ufcma}(\lambda)$   $\diamond$

Assume that these two are distinguishable by  $\mathcal{D}$ . So we could have  $\mathcal{D}'$  which is capable, with the following game, of distinguishing a pseudo-random function from a true random function:

After  $\mathcal{D}'$  receive  $\phi'$  from  $\mathcal{C}$ , he has to use the distinguisher  $\mathcal{D}$  to distinguish the PRF function from the random one. So he says to  $\mathcal{D}$  if  $\phi^* = \phi'$  or not, and  $\mathcal{D}$  now is capable of understanding which game he is playing.

**Lemma 11.** *For all efficient adversaries  $\mathcal{P}[\mathcal{HYB}_1(\lambda) = 1] \leq 2^{-l}$*   $\diamond$

This is true because attacker has to predict the output  $R(m^*)$  on a fresh input  $m^*$  and to send to the Challenger this couple to win the game. This can happen, at most, with probability  $\frac{1}{2^l}$ .  $\square$

This was for fixed length messages, since we can encrypt messages long  $n$ . In the next subsection, we will see how to create a UFCMA-secure MAC for variable length messages.

## 4.15 Domain extension

Assume  $m = (m_1, \dots, m_t) \in (\{0, 1\}^n)^t$  for some  $t \geq 1$ . How can we tag  $m$  given just  $\text{Tag}_k : \{0, 1\}^n \rightarrow \{0, 1\}^l$ ?

We can try various attempts:

- XOR all blocks:  $\phi = \text{Tag}_k(\bigoplus_{i=1}^t m_i)$ .  
This is not secure cause given  $(m, \phi)$  it is possible to find  $m^* \neq m$  s.t.

$$\bigoplus m_i = \bigoplus m_i^*$$

and output this the couple  $(m^*, \phi)$  to win.

- Let  $\phi_i = \text{Tag}_k(m_i)$  and the final message of the challenge has this form :  $(m, \phi = (\phi_1, \dots, \phi_t))$ .  
This is not secure. Given  $m = (m_1, \dots, m_t)$ , this message has an unique  $\phi = (\phi_1, \dots, \phi_t)$ , and if I swap  $m_1$  and  $m_t$  I obtain a fresh new message,

with a fresh new tag  $\phi' = (\phi_t, \phi_2, \dots, \phi_{t-1}, \phi_1)$ . Using this new couple, the game is won.

- Try with  $\phi_i = \text{Tag}_k(i||m_i)$ , authenticating the position of the block .  
But this is not secure, and can be showed in **just 2 queries**. (I solved this in class during the break, with  $t + 1$  queries:  $t$  for retrieving the partial tag of the submessage+position , and the last query to merge all the obtained results in a fresh new message. But this solution can be improved.)  
(UPDATE: I send  $m = m_{1_1}, \dots, m_{1_t}$  and I save the corresponding  $\phi$ . Then I send  $m' = m_{2_1}, \dots, m_{2_t}$  and I save the  $\phi'$ . Now I forge the new fresh prince of Bel Air  $m^* = m_1, m_2, m_2, \dots, m_2$  and I can forge also a valid  $\phi^*$  because I have all the signed parts of this new tag. )

Now I feel cool in Los Angeles and I want to explore a new **IDEA**:  
the design of a shrinking functions family

$$\mathcal{H} = \{h_s : \{0, 1\}^{nt} \rightarrow \{0, 1\}^n\}_{s \in \{0, 1\}^\lambda}$$

which can be used to shrink variable length messages and then apply a PRF on them.

This idea is cool, and I consider the induced family

$$\mathcal{F}(\mathcal{H}) = \{F_k(h_s(.))\}$$

**Question 3.** Which are the properties of this family?

The main problem are *collisions* , since for each  $m \in \{0, 1\}^{nt}$  it should be hard to find  $m' \neq m$  such that  $h_s(m) = h_s(m')$ .

But we know that collisions exist, because we are trying to create a function

$$\text{Tag}_{k,s}(m) = F_k(h_s(m))$$

which maps elements in  $\{0, 1\}^{nt}$  to the elements in  $\{0, 1\}^t$ , and since the second set is smaller, for the pidgeonhole principle, there will be elements of  $\{0, 1\}^t$  which will be reached by more than one element of  $\{0, 1\}^{nt}$ .

To overcome this problem, we can consider 2 ways:

- assume collisions are hard to find given  $s \in \{0, 1\}^\lambda$  publicly, and we have a *collision resistant hashing*;
- let  $s$  be secret, and assume collisions are hard to find because it is hard to know how  $h_s$  works.

**Definition 8.**  $\mathcal{H}$  is called **universal** family if

$$\forall x, x' \in \{0, 1\}^{nt} \text{ such that } x \neq x'$$

$$\mathcal{P}_{s \leftarrow \{0, 1\}^\lambda} [h_s(x) = h_s(x')] \leq \varepsilon$$

◇

For  $\varepsilon = 2^{-n}$  we call it **perfectly universal**.  
For  $\varepsilon \in \text{negl}(\lambda)$  we call it **almost universal** (or **AU** ).

**Exercise 14.** Show that any pairwise independent hash function is perfectly universal. (should I use *Col* for solving this? What is the difference and when I should use *Col* instead of one-shot-probability?) **ASK FOR SOLVING PROPERLY** (Thoughts: when I ask *what's the probability that , chosen 2 distinct  $x$ -es, their hashes are the same on a certain value?* , maybe I have to use one-shot, because one-shot refers to the prob. that the two inputs collide on a specific value, even if not specified.

Instead, if I consider *what's the prob. that , chosen 2 distinct  $x$ -es, their hashes are the same?*, maybe I have to calculate all the possible collisions, because I want to know if the 2 inputs can collide in general. )

**Theorem 15.** Assuming  $\mathcal{F}$  is a PRF with  $n$ -bit domain and  $\mathcal{H}$  is AU, then  $\mathcal{F}' = \mathcal{F}(\mathcal{H})$  is a PRF (and , if used in a MAC as tag function, makes it UFCMA) on  $nt$ -bit domain (for  $t \geq 1$ ).  $\diamond$

We want to show that  $\mathcal{F}' = \mathcal{F}(\mathcal{H})$  is a PRF , so we want to show that

$$\text{Real}_{\mathcal{F}, \mathcal{A}}(\lambda) \approx_c \text{Rand}_{\mathcal{R}', \mathcal{A}}(\lambda)$$

*Proof.* Consider these 3 experiments/games:

Figure 4.26:  $\text{Real}_{\mathcal{F}, \mathcal{A}}(\lambda)$

Figure 4.27:  $\mathcal{HYB}_{\mathcal{R}, \mathcal{A}}(\lambda)$

Figure 4.28:  $\text{Rand}_{\mathcal{R}', \mathcal{A}}(\lambda)$

**Lemma 12.**  $Real \approx_c \mathcal{HYB}$

◇

**Exercise 16.** Prove it!

**Lemma 13.**

$$\mathcal{HYB} \approx_c Rand$$

◇

These 2 experiments are very similar but for the encryption step. If I send 2 consecutive queries to both the experiments, while  $Rand$  will give me

- the same  $y$  with the same  $x$  or
- the same  $y$  with different  $x_1 \neq x_2$  but with very low probability,

$\mathcal{HYB}$  could return the same  $y$ :

- with the same  $x$  input or
- with different  $x_i \neq x_j \Rightarrow h_s(x_i) \neq h_s(x_j)$  but with very low probability (because  $R$  is a random function), or
- with different  $x_i \neq x_j$  but with the same  $h_s(x_i) = h_s(x_j)$ ,

We want to show that the last item doesn't happen too often, and that these 2 experiments are distinct for a negligible factor.

*Proof.* Let **BAD** be the event that

$$\exists i, j \in [q] \text{ with } i \neq j \text{ s.t. } h_s(x_i) = h_s(x_j)$$

As long as **BAD** doesn't happen, the function  $R$  is run as a sequence of distinct points  $R(h_s(x_1)), \dots, R(h_s(x_q))$ .

So in this case the distribution if the 2 games is identical, and it suffices to show that  $\mathcal{P}[BAD] \in \text{negl}(\lambda)$ .

The event **BAD**, which happens during a game made of  $q$  queries and  $q$  replies, is the same as collecting all the  $q$  queries, choosing the seed and then looking for collisions. If interpreted in this way,

$$\begin{aligned} \mathcal{P}[BAD] &= \mathcal{P}_s[\exists x_i \neq x_j, h_s(x_i) = h_s(x_j)] \leq \\ &\leq \sum_{i,j} \underbrace{\mathcal{P}[h_s(x_i) = h_s(x_j)]}_{h_s \text{ is AU by definition}} \leq \\ &\leq \binom{q}{2} \text{negl}(\lambda) \in \text{negl}(\lambda) \end{aligned}$$

□

So now we have  $Real \approx_c \mathcal{HYB} \approx_c Rand$

□

Now we want to show a possible shrinking/hash function which can be used in a UFCMA-secure MAC. In order to be used in a UFCMA-secure MAC as the input of a PRF, this function must be part of an **almost universal** family.

#### 4.15.1 $\mathcal{H}$ family using Galois Fields

**Construction 3.** Take  $\mathbb{F} = GF(2^n)$ , a *Galois field* of  $2^n$  elements. Let  $m = (m_1, \dots, m_t) \in \mathbb{F}^t$  and  $s = (s_1, \dots, s_t) \in \mathbb{F}^t$ . We state that

$$h_s(m) = \sum_{i=1}^t s_i m_i = \langle s, m \rangle = q_m(s)$$

◇

A generic *galois field* has very interesting properties, like the following :

- addition of two elements is like applying the XOR operation on their binary forms;
- multiplication of two elements is like the product *mod*  $2^n$

Now, since this family must be almost universal to be used as part of UFCMA-secure MAC protocol, collisions must happen a negligible amount of time.

Suppose we have a collision with two different messages:

$$\sum_{i=1}^t m_i s_i = \sum_{i=1}^t m'_i s_i$$

Let  $\delta_i = m_i - m'_i$ , assuming without loss of generality that  $\delta \neq 0$ . Now we have that, when a collision happens,

$$\begin{aligned} \sum_{i=1}^t m_i s_i = \sum_{i=1}^t m'_i s_i &\Leftrightarrow \sum_{i=1}^t m_i s_i - \sum_{i=1}^t m'_i s_i = 0 \Leftrightarrow \\ &\sum_{i=1}^t \delta_i s_i = 0 \end{aligned}$$

Taking  $m, m'$  such that  $m \neq m'$  means that  $m$  is distinct from  $m'$  at least for one subsequence  $m_i \neq m'_i$ .

So we can assume, without loss of generality, that  $i = 1$  is an index (or the only index) which  $m$  and  $m'$  differ on.

So we can split the last summation in 2 parts, choosing  $\delta_1 s_1$  as the first element and  $\sum_{i=2}^t \delta_i s_i$  as second element:

$$\begin{aligned} \delta_1 s_1 + \sum_{i=2}^t \delta_i s_i &= 0 \Leftrightarrow \\ \delta_1 s_1 &= - \sum_{i=2}^t \delta_i s_i \Leftrightarrow \\ s_1 &= \frac{- \sum_{i=2}^t \delta_i s_i}{\delta_1} \end{aligned}$$

and this means that when a collision happens  $s_1$  must be exactly equal to the second member of the equation, which is an element of  $\mathbb{F}$ . But since every seed is chosen at random among  $\mathbb{F}$ , what's the probability of picking the element  $s_1$  which zeroes the above equation ?  
This probability is just  $\frac{1}{|\mathbb{F}|} = \frac{1}{2^n} \in \text{negl}(\lambda)$ .

### $\mathcal{H}$ with Galois fields elements and polynomials

**Construction 4.** Take  $\mathbb{F} = GF(2^n)$ , a *Galois field* of  $2^n$  elements.  
Let  $m = (m_1, \dots, m_t) \in \mathbb{F}^t$  and  $s \leftarrow \mathbb{F}^t$ . We state that

$$h_s(m) = \sum_{i=1}^t s^{i-1} m_i$$

◇

**Exercise 17.** Prove that this construction is **almost universal**.

(possible proof: to be almost universal, looking at the definition, collisions with  $m \neq m'$  must be negligible.

So consider a collision as above: it must be true that

$$\sum_{i=1}^t m_i s^{i-1} = \sum_{i=1}^t m'_i s^{i-1} \Leftrightarrow \sum_{i=1}^t m_i s^{i-1} - \sum_{i=1}^t m'_i s^{i-1} = 0 \Leftrightarrow q_{m-m'}(s) = 0$$

How can we make a polynomial equal to 0? We have to find the **roots** of the polynomial, which we know are at most the **grade** of the polynomial. So, the grade of this polynomial is  $t - 1$ , and the probability of picking a root from  $\mathbb{F}$  as seed of  $h_s(\cdot)$  is

$$\mathcal{P}[s = \text{root}] = \frac{t-1}{2^n} \in \text{negl}(\lambda)$$

)

# Lesson 10

## 4.16 Domain extension for PRFs/MACs

*Almost universal approach* : I have a family  $\mathcal{F}(\mathcal{H})$  with  $\mathcal{H}$  AU and with PRF  $f \in \mathcal{F}$ .

*Computational AU* : we want to build a family  $\mathcal{H}$  using some other PRFs. We expect to have:

- $\mathcal{P}[h_s(m) = h_s(m'), s \leftarrow \{0, 1\}^\lambda, (m, m') \leftarrow A(1^\lambda)] \in \text{negl}(\lambda)$ ;
- We need two PRFs. One is  $F_k$ , and the other is  $F_{sj}$

=====

something related to  $f_s(1, \cdot)$  and  $f_s(0, \cdot)$ , but I didn't get it.

=====

### 4.16.1 XOR mode

Assume that we have this function

$$h_s(m) = F_s(m_1||1) \oplus \dots \oplus F_s(m_t||t)$$

so that the input to the PRF  $F_s(\cdot)$  is  $n + \log_2 t$  bytes long.

**Lemma 14.** *Above  $\mathcal{H}$  is computational AU if  $\mathcal{F}$  is a PRF.* ◇

**Exercise 18.** Prove this !

Possible proof:

we have to show that

$$\mathcal{P}[h_s(m) = h_s(m')] \in \text{negl}(\lambda)$$

with  $m \neq m'$ .

This means that

$$\begin{aligned} \mathcal{P}[F_s(m_1||1) \oplus \dots \oplus F_s(m_t||t) = F_s(m'_1||1) \oplus \dots \oplus F_s(m'_t||t)] = \\ = \mathcal{P}[F_s(m_i||i) \oplus F_s(m'_i||i) = \alpha] = \bigoplus_{j=1, j \neq i}^t F_s(m_j||j) \oplus F_s(m'_j||j) \end{aligned}$$

for each  $i \in [1, t]$ .

But  $\alpha$  is one unique random number chosen over  $2^n$  possible candidates, so the collision probability is negligible.

#### 4.16.2 CBC MAC

This is part of the standard, used in TLS. It's used with a PRF  $F_s$ , setting the starting vector  $IV = 0^n = c_0$  and running this PRF as part of CBC. The output of the CBC process is just the last block:

$$h_s(m_1, \dots, m_t) = F_s(m_t \oplus F_s(m_{t-1} \oplus \dots \oplus F_s(m_2 \oplus F_s(m_1 \oplus IV))))$$

**Lemma 15.** *CBC MAC defines completely an AU family.*

(not proven) ◇

We can use this function to create an **encrypted CBC**, or **E-CBC** :

$$E - CBC_{K,S}(m) = F_k(h_s^{CBC}(m))$$

**Theorem 19.** *Actually if  $\mathcal{F}$  is a PRF, CBC-MAC is already a MAC with domain nt for arbitrary but fixed  $t \in \mathbb{N}$ .*

(not proven) ◇

#### 4.16.3 XOR MAC

Instead of  $\mathcal{F}(\mathcal{H})$  now the  $Tag()$  function outputs  $\phi = (\eta, F_k(\eta) \oplus h_s(m))$  where  $\eta \leftarrow \{0, 1\}^n$  is random and it's called *nonce* .

When I want to authenticate, I should send the

$$(m, (\eta, F_k(\eta) \oplus h_s(m)))$$

couple.

When I want to verify a message and I get the couple  $(m, (\eta, v))$ , I just check that  $v = F_k(\eta) \oplus h_s(m)$ . It should be hard to find a value called  $a$  such that, given  $m \neq m'$ ,

$$h_s(m) \oplus a = h_s(m')$$

In fact, since an adversary who wants to break this scheme has to send a valid couple  $(m^*, \phi^*)$  after some queries, he could:

- ask for message  $m$  and store the tag  $(\eta, F_k(\eta) \oplus h_s(m))$
- try to find  $a = h_s(m) \oplus h_s(m')$  and modify the previous stored tag adding  $v \oplus a$ ,

so now he could send the authenticated message

$$(m', (\eta, F_k(\eta) \oplus h_s(m')))$$

which is a valid message.

=====

WHAT IS IT ABOUT?

**Lemma 16.** *XOR mode gives computational AXU (Almost Xor Universal).*  
*(not proven)* ◇

WAHT DOES IT MEAN AXU?? Has something to do with the first 2 definitions given in the start of this subsection ? =====

**Theorem 20.** *If  $\mathcal{F}$  is a PRF and  $\mathcal{H}$  is computational AXU, then XOR-MAC is a MAC.*  
*(not proven)* ◇

=====

NOT CLEAR WHAT TO DO

**Exercise 21.** Now with variable input lenght:

- AXU based XOR mode
  - $\mathcal{F}(\mathcal{H})$  is insecure with polynomial construction  $h_s(m) = q_m(s)$ , but can be fixed.
  - CBC-MAC not secure. (exercise)
  - E-CBC is secure.
- =====

## 4.17 Chosen Ciphertext Attack security

In this kind of attack, the adversary has a decryption capability added to the previous encryption capability. A scheme which is CCA-secure is also **non-malleable**, since the attacker cannot modify the obtained ciphertexts to obtain new valid ciphertexts.

Figure 4.29:  $\text{Game}_{\Pi, \mathcal{A}}^{cca}(\lambda, b)$

**Exercise 22.** Show that  $(r, F_k(r) \oplus m)$  which is CPA-secure, is not CCA-secure.

*Proof.* with

$$\begin{aligned}
Dec(k, c) &= F_k(r_\alpha) \oplus s_\alpha \oplus 1000\dots000 = \\
&F_k(r_\alpha) \oplus F_k(r_\alpha) \oplus m_b \oplus 1000\dots000 = \\
&m_b \oplus 1000\dots000
\end{aligned}$$

At this point we have that the output is

- 1000...000 if  $m_b$  was 000...000
- 0111...111 if  $m_b$  was 0111...111

□

## 4.18 Authenticated encryption

**Idea:** what if we combine the target of authenticity with the target of encryption?

The first property is satisfied when the receiver is able to understand if the received message was sent exactly by the trusted sender; the last property is satisfied when no information of the sent message is contained in the ciphertext, thus only the chosen receiver can fully read the original sent message.

If we build up a schema with these 2 properties, we can obtain a new schema which should be *cpa-secure* (to enforce the encryption/privacy property) and essentially secure against forgeries of chosen message attacks (to enforce the authentication property).

In particular, a successful forgery can be obtained winning the following game:

Figure 4.30:  $Game_{\Pi, \mathcal{A}}^{auth}(\lambda)$

meaning that the  $c^*$  challenge ciphertext should be a **fresh** and a valid one ciphertext, considering that the  $Dec(\cdot)$  function is defined as

$$Dec : \mathcal{K} * \mathcal{C} \rightarrow M \cup \{\perp\}$$

where  $\perp$  represents invalid/meaningless messages.

In the end, we want that our *authenticated encryption schema* is cpa-secure and has this last property, called **strong unforgeability** or **auth**.

**Theorem 23.** Let  $\Pi$  be an SKE (shared key encryption). If  $\Pi$  has **CPA** + **auth** security, then it also has **CCA** security.  $\diamond$

**Exercise 24.** Prove it!

**Hint:** consider the experiment where  $Dec(k, c)$ :

- if  $c$  not fresh ( i.e. output of previous encryption query  $m$ , output  $m$ )
- else output  $\perp$

=====

TO DO AND TO PROVE

Approach: reduce cca to cpa; given  $D^{cca}$ , we can build  $D^{cpa}$ .  $D^{cca}$  will ask decryption queries, but  $D^{cpa}$  can answer just with these two properties shown above, so it can reply just if he asked these  $(c, m)$  before to its challenger  $\mathcal{C}$ .

=====

#### 4.18.1 Three approaches to authenticated encryption

Let  $\Pi_1$  be a **cpa-secure** SKE and  $\Pi_2$  be a **auth** MAC schema.

We have 3 ways to combine these 2 schema to obtain a new one:

1. **Encrypt-and-MAC** :

$$\begin{aligned} c &\leftarrow \text{\$Enc}(k_1, m) \\ \phi &= \text{\$Tag}(k_2, m) \\ c^* &= (c, \phi) \end{aligned}$$

2. **MAC-then-encrypt** :

$$\begin{aligned} \phi &= \text{\$Tag}(k_2, m) \\ c &\leftarrow \text{\$Enc}(k_1, \phi \| m) \\ c^* &= c \end{aligned}$$

=====

DA RIVEDERE: come i  $\phi$  sono randomici o no? A guardare la prima parte della prossima lezione , sembrerebbe di si.

3. **Encrypt-then-MAC** :

$$\begin{aligned} c &\leftarrow \text{\$Enc}(k_1, m) \\ \phi &\leftarrow \text{\$Tag}(k_2, c) \\ c^* &= (c, \phi) \end{aligned}$$

=====

In a paper is clearly stated that the first solution doesn't work taking random combination of CPA-secure and MAC schemes, because there are couple which, mixed, are not CCA-secure. Furthermore the second solution doesn't work for

the same above reason, even if it's now part of the standard.

Instead, the third solution works always for a CPA-secure scheme  $\Pi_1$  and strong unforgeability scheme  $\Pi_2$  which, combined, they generate the final scheme  $\Pi$ .

**Theorem 25.** *If  $\Pi$  is made combining  $\Pi_1$  cpa-secure and  $\Pi_2$  auth-secure as stated in the third point, then  $\Pi$  is cpa-secure and auth-secure .*  $\diamond$

*Proof.* By reduction, we negate that  $\Pi$  has both the properties and we find the contradiction.

Suppose now that  $\Pi$  hasn't the cpa-security property.

Here we are supposing that  $\mathcal{A}$  can break the cpa-security of a generic  $\Pi_1$  scheme used by  $\mathcal{C}$ , while  $\mathcal{A}'$  can break the cpa-security of a generic scheme  $\Pi$ .  $\mathcal{C}$  can generate the  $Tag(k_2, .)$  function, randomly choosing  $k_2$  and simulating  $\Pi$ .

=====

REVIEW

Professor says that we have to show that  $Game^{cpa}(\lambda, 0) \approx_c Game^{cpa}(\lambda, 1)$ , but why??? Isn't this proof enough?

=====

Proved for the cpa-security property, now we have to prove, in a similar way, that the auth property must be holded by  $\Pi$  if  $\Pi_2$  is an auth-secure scheme.

**Exercise 26.** Prove it!

Similar to the cpa-security proof.

□

# Lesson 11

## 4.19 Authenticated encryption (Age of Ultron)

Last time we proved CPA-security of  $\Pi$ . Today we will explore the *auth* property. Consider  $\Pi$  as

$$\begin{aligned} Enc &: \{0,1\}^\lambda * \mathcal{M} \rightarrow \mathcal{C} \\ Tag &: \{0,1\}^\lambda * \mathcal{C} \rightarrow \Phi \end{aligned}$$

**Lemma 17.** *If  $Tag(.,.)$  is **EUF-CMA**, then  $\Pi$  has *auth*-property.*  $\diamond$

What is **EUF-CMA** ?

It's a property similar to **uf-cma**, but now I want that the challenge message  $(m^*, \phi^*)$  is made by a fresh  $m^*$  and a valid **fresh**  $\phi^*$ .

The difference is that in **ufcma** we didn't care about the freshness of  $\phi^*$ .

*Proof.* Suppose  $\Pi$  has not the *auth* property.

So we have an  $\mathcal{A}'$  which can win the **auth** challenge of  $\Pi$ .

On the other hand, we have a  $\Pi_2$  schema which uses an **euf-cma**  $Tag(.,.)$  function.

So, by reduction, we show that

The game returns 1 IFF

$$c^* \leftarrow Enc(k_1, .) \wedge \phi^* \leftarrow Tag(k_2, c^*) \wedge (c^*, \phi) \notin \{(c, \phi)\}$$

From  $\mathcal{A}^{auth}$  perspective, all the couples  $(c_i, \phi_i)$  received are made with the following schema:

$$c_i \in Enc(k_1, m \in \mathcal{M}) \wedge \phi_i \leftarrow \$Enc(k_2, c_i)$$

Since  $\mathcal{A}^{auth}$  wins  $Game^{auth}$ , the challenge couple  $(c^*, \phi^*)$  which breaks  $Game^{auth}$  will be produced to be decrypted as

$$Dec(k, (c^*, \phi^*)) \rightarrow Dec(k_1, c^*) \in \mathcal{M} \wedge Dec(k_2, \phi^*) = c^*$$

But if this happens, then  $\mathcal{A}$  can use the same challenge couple of  $\mathcal{A}^{auth}$  to win  $Game^{ufcma}$ , which is impossible.

It could happen that, for  $c^* = c$  previously seen,  $\phi^*$  is a new fresh tag, never seen before. Just in this case the *auth* game would be valid because  $(c^*, \phi^*)$  would have never been seen before, but **not** the *eufcma* game, because  $c^*$  was previously sent to the challenger.

□

Now we want an *ufcma* secure scheme able to resist against message-tag challenge couples where the tag is fresh but the message has been already requested to the challenger.

## 4.20 Pseudorandom permutations

Pseudorandom permutations are like PRFs, but efficiently invertible. Consider the following family of functions:

$$\mathcal{F} = \{F_k : \{0, 1\}^n \rightarrow \{0, 1\}^n\}_{k \in \{0, 1\}^\lambda}$$

Figure 4.31:  $Real_{\mathcal{F}, \mathcal{A}}(\lambda)$

Figure 4.32:  $Ideal_{\mathcal{P}, \mathcal{A}}(\lambda)$

and the two games are indistinguishable

$$Real_{\mathcal{F}, \mathcal{A}}(\lambda) \approx_c Ideal_{\mathcal{F}, \mathcal{A}}(\lambda)$$

### 4.20.1 Feistel Network

Let  $F : \{0, 1\}^n \rightarrow \{0, 1\}^n$  and  $\psi_F$  the invertible function

$$\begin{aligned}\psi_F(\overbrace{x}^{\text{n bits}}, \overbrace{y}^{\text{n bits}}) &= (y, x \oplus F(y)) = (x', y') \\ \psi_F^{-1}(\overbrace{x'}^{\text{n bits}}, \overbrace{y'}^{\text{n bits}}) &= (F(x') \oplus y', x') = (x, y)\end{aligned}$$

Is this function pseudorandom?

This is not pseudorandom, because the first  $n$  bits of the output of  $\psi_F$  are always equal to  $y$ , while in a PRF the probability that, given two different  $(x, y)$  and  $(x', y)$  in input, the first bits are equal is very low.

=====

FEISTEL IMAGE

=====

The  $l - th$  level outputs something like

$$\psi_F[l](x, y) = \psi_{F_{k_l}}(\psi_{F_{k_{l-1}}}(\dots(\psi_{F_{k_1}}(x, y))\dots))$$

Two XORed rounds of this function don't create a PRP. In particular, imagine 2 queries  $(x, y)$  and  $(x', y)$  such that

$$\psi_{F, F'}(x, y) \oplus \psi_{F, F'}(x', y) = (x \oplus F(y) \oplus x' \oplus F(y), \dots)$$

Since for 2 random queries with the same  $y$ , the first member of the output is always equal to  $x \oplus x'$  with probability 1, this XORed rounds cannot constitute a PRP (which, instead, for 2 queries with the same second member outputs a first member equal to  $x \oplus x'$  with negligible probability).

**Lemma 18.** *For every **unbounded** distinguisher making  $q \in \text{poly}(\lambda)$  queries, the following are statistically close as long as  $y_1, \dots, y_q$  are **y-nique**, i.e.  $\forall i \neq j, y_i \neq y_j$*   $\diamond$

figures

# Lesson 15

## 4.21 Public key encryption recap

$\text{Game}_{\Pi, \mathcal{A}}^{\text{pke-cca}}$ :

Figure 4.33: CCA on a PKE scheme

(Reminder): Encryptions are made like this:  $\text{Enc}(k, m) = (r, F_k(r) \oplus m)$ ,  $r \simeq \text{Unif}(\{0, 1\}^\lambda)$ .

Every time an encryption is made, a fresh value  $r$  is picked UAR.

### 4.21.1 Trapdoor permutation

A TDP (TrapDoor Permutation) is a OWP family structured has these features:

- A key pair is chosen UAR by a key generator algorithm:  $(pk, sk) \leftarrow \mathcal{KGen}(1^\lambda)$
- There is a function family  $f_{pk} \subseteq (V_{pk} \rightarrow V_{pk})$  such that:
  - Computing  $f_{pk}$  is efficient
  - Sampling from the domain ( $x \leftarrow V_{pk}$ ) is efficient
- There is an efficient function  $g_{sk}$  that “inverts”  $f_{pk}$  ( $sk$  is the “trapdoor”):

$$g(sk, f(pk, x)) = x$$

- No efficient adversary is able to invert  $f_{pk}$  without knowing  $sk$

Note: Since  $pk$  is public, any adversary gets the capability of encrypting messages for free, without requiring an external challenger/oracle!

Therefore, if left deterministic, a TDP is not CPA-secure.

Here, in this scheme, we combine randomness and the notion of hardcore predicate  $\mathfrak{hc}$ :

- $(pk, sk) \leftarrow \mathcal{KGen}(1^\lambda)$
- $r \leftarrow \Xi_{pk}$
- $c := \text{Enc}(pk, m) = (f_{pk}(r), \mathfrak{hc}(r) \oplus m)$
- Correctness:  $\text{Dec}(sk, c) = \mathfrak{hc}(g_{sk}(c_1)) \oplus c_2$

Theorem: if  $(\mathcal{KGen}, f, g)$  is a TDP, and  $\mathfrak{hc}$  is hardcore for  $f$ , then the above scheme is CPA-secure.

Proof: (Exercise)

### 4.21.2 TDP examples

One example stems from the factoring problem: let's look again at  $\mathbb{Z}_n^\times$ , where  $n = pq$ ,  $p, q \in \mathbb{P}$ ;

Theorem (Chinese remainder, or CRT): The following isomorphisms to  $\mathbb{Z}_n^\times$  are true:

- $\mathbb{Z}_n \simeq \mathbb{Z}_p \times \mathbb{Z}_q$
- $\mathbb{Z}_n^\times \simeq \mathbb{Z}_p^\times \times \mathbb{Z}_q^\times$

Note that the theorem is more general, and holds for any  $p, q$  that are co-prime.

How to use this theorem for constructing a PKE scheme:

Reminder (Euler's theorem):  $\forall x \in \mathbb{Z}_n \implies x^{\varphi(n)} = x \pmod n$

Reminder:  $\forall p, q \in \mathbb{P} \implies \varphi(pq) = (p-1)(q-1)$

So let  $a$  be the public key such that  $\gcd(a, \varphi(n)) = 1$ , then  $\exists! b \in \mathbb{Z}_n : ab = 1 \pmod{\varphi(n)}$ ,  $d$  will be our private key.

Define encryption as  $f(a, m) = m^a \mod n$ , and then decryption as  $g(b, c) = c^b \mod n$

Observe that  $g(b, f(a, m)) = (m^a)^b = m^{ab} = m \mod n$ , because  $ab = 1 \mod \varphi(n)$

So we conjecture that the above is a valid TDP-based PKE scheme. This is actually called the “RSA assumption”:

Figure 4.34: Depiction of the RSA assumption

Relation to the factoring problem:  $\text{RSA} \implies \text{FACT}$

Proof: Given  $p, q$ , an adversary can compute  $\varphi(n) = (p-1)(q-1)$ , and then find the inverse of the public key in  $\mathbb{Z}_{pq}^\times$ .

It hasn't been proven that  $\text{FACT} \implies \text{RSA}$

## 4.22 Textbook RSA

This is an insecure toy example of the more complex *RSA* (Rivest Shamir Adleman) algorithm. The key generation algorithm:  $\text{KGen} = \text{GenRSA}(1^\lambda)$  outputs  $P_k = (n, e)$  and  $S_k = d$ , then we have

$$\text{Enc}(P_k, m) = m^e \pmod{n}$$

$$\text{Dec}(S_k, c) = c^d \pmod{n}$$

Since the output of Enc is deterministic this is **not CPA secure**! However it can be used with HARD-CORE Predicate.

Preprocess the message to add randomness:

$$\hat{m} = r || m \text{ where } r \leftarrow \$\{0, 1\}^l$$

now Enc is not deterministic.

**Facts:**

1.  $l \in \text{super}(\log(\lambda))$  otherwise it is possible to bruteforce in PPT.
2. If  $m \in \{0, 1\}$  then I can prove it CPA secure under RSA (just use standard TDP)
3. If  $m$  is "in the middle" ( $\{0, 1\} \leq m \leq \{0, 1\}^l$ ) RSA is believed to be secure and is standardized (PKCS#1,5)
4. Still not CCA secure!

#### 4.22.1 Trapdoor Permutation from Factoring

Let's look at  $f(x) = x^2 \pmod{n}$  where  $f : \mathbb{Z}_n^* \rightarrow \mathbb{QR}_n(\subset \mathbb{Z}_n^*)$ , this is not a permutation in general.

Now let's consider the Chinese Remainder Theorem (CRT) representation:

$$\begin{aligned} x &= (x_p, x_q) \rightarrow x_p \equiv x \pmod{p}, x_q \equiv x \pmod{q} \\ f(x) &= x^2 \pmod{p}; x \leftarrow \$_{Z_p^*} \end{aligned}$$

Since  $\mathbb{Z}_p^*$  is cyclic I can always write:

$$\begin{aligned} \mathbb{Z}_p^* &= \{g^0, g^1, g^2, \dots, g^{\frac{p-1}{2}-1}, g^{\frac{p-1}{2}}, \dots, g^{p-2}\} \\ \mathbb{QR}_p &= \{g^0, g^2, g^4, \dots, \underbrace{g^{p-3}}_{g^{\frac{p+1}{2}-1} \text{ in } \mathbb{Z}_p^*}, \underbrace{g^0}_{g^{\frac{p-1}{2}} \text{ in } \mathbb{Z}_p^*}, \dots\} \\ |\mathbb{QR}_p| &= \frac{p-1}{2} \end{aligned}$$

Moreover since  $(g^{\frac{p-1}{2}})^2 \equiv 1 \pmod{p}$  then  $g^{\frac{p-1}{2}} \equiv -1 \pmod{p}$ .

Now assume  $p \equiv 3 \pmod{4}$  ( $[*]p = 4t + 3$  CRT), then squaring  $\text{Mod } p$  is a permutation because, given  $y = x^2 \pmod{p}$  if I compute:

$$\begin{aligned} (y^{t+1})^2 &= \underbrace{y^{2t+2}}_{[*] \ 2t+2 = \frac{p-3}{2} + 2 = \frac{p+1}{2} = \frac{p-1}{2} + 1} = (x^2)^{\frac{p-1}{2}+1} = 1x^2 = x^2 \\ &\implies x = \pm y^{t+1} \end{aligned}$$

But only 1 among the above  $\pm y^{t+1}$  is a square, this is because  $\frac{p-1}{2}$  is odd.

**Lemma 19.**  $\forall z, z \in \mathbb{QR}_p \text{ IFF } -z \notin \mathbb{QR}_p$   $\diamond$

=====

#### 4.22.2 Rabin's Trapdoor permutation

Now we study a one way function built on previous deductions about number theory and modular arithmetic.

The *Rabin trapdoor permutation* is defined as

$$f : \mathbb{Z}_n^* \rightarrow \mathbb{Z}_n^* f(x) = x^2 \pmod{n}$$

where  $n = p * q$  for primes  $p, q \equiv 3 \pmod{4}$ .

T0D0 2: label related to a previous construction

We can observe that the image of this function is a subset of  $\mathbb{Z}_n^*$ .

For the **Chinese remainder theorem**, we can consider values modulo  $N = pq$  as values modulo  $p$  and values modulo  $q$ .  
So now consider

$$f : \mathbb{Z}_p^* \rightarrow \mathbb{Z}_p^* f(x) = x^2 \bmod p$$

The image of the function  $f$  exactly matches the definition of **quadratic residues**, since

$$f\text{'s image set} = \mathbb{QR}_p = \{y : y \equiv x^2 \bmod p, x \in \mathbb{Z}_p^*\}$$

We can observe the same for  $\mathbb{Z}_q^*$ .

So for **Chinese remainder theorem** it is possible to state that  $f$  maps as follows

$$x = (x_p, x_q) \mapsto (x_p^2, x_q^2)$$

As before, the image of  $f$  is exactly

$$\mathbb{QR}_n = \{y : \exists x : y = x^2 \bmod n\}$$

For the previous observations, it's possible to state the following **Fact**:

$$y \leftarrow \mathbb{QR}_n \Leftrightarrow y \in \mathbb{QR}_p \wedge y \in \mathbb{QR}_q$$

This is important because if we try to invert the function  $f$ , among the hypothetical 4 possible values

$$f^{-1}(y) = \{(x_p, x_q), (-x_p, x_q), (x_p, -x_q), (-x_p, -x_q)\}$$

only 1 out of these above 4 values is a quadratic residue because only one of  $-x_k, x_k$  is a quadratic residue for  $k = q, p$ .

**T0D0 3:** label to previous fact

Therefore, we have that the Rabin's TDP is a permutation, and that the cardinality of  $\mathbb{QR}_n$  is  $\frac{|\mathbb{Z}_n^*|}{4}$ .

Furthermore, with the following claim we can state that the Rabin cryptosystem is as secure as the hardness of factoring.

**Claim 1.** *Given  $x, z$  such that  $x^2 \bmod n \equiv z^2 \bmod n \equiv y \bmod n$ ,*

$$x \neq \pm z \Rightarrow \text{we can factor } n$$

◇

*Proof.* For the previous statement 4.22.2, since  $f^{-1}(y)$  has only one value out of four, summing two distinct elements  $x, z$  in the domain of function  $f$  generates only 2 possible values:

$$x + z \in \{(0, 2x_q), (2x_p, 0)\}$$

Now assume  $x + z = (2x_p, 0)$  without loss of generality, since the proof for the other case is the same.

We have that  $x + z \equiv 0 \pmod{q}$  and  $x + z \not\equiv 0 \pmod{p}$ .

But then  $\gcd(x + z, n) = q$ , and we obtain  $q$ .  $\square$

**Theorem 27.** *Squaring mod  $n$  (where  $n$  is a bloom integer<sup>5</sup>) is a **trapdoor permutation** under factoring.*  $\diamond$

In other words

Factoring is hard  $\Rightarrow$  inverting  $f(x)$  is hard

The following proof is by contraddiction.

*Proof.* Assume that exists an adversary PPT such that

$$\mathcal{P}[x^2 = y : (p, q, n) \leftarrow \text{\$Genbloom}(1^\lambda), y \leftarrow \text{\$QR}_n, x \leftarrow \mathcal{A}(y)] \geq \frac{1}{\text{poly}(\lambda)}$$

But then we can build the following reduction:

T0D0 4: check the correctness of the image

$\square$

---

<sup>5</sup> a bloom integer  $n$  is  $n = p, q$  for  $p, q = 3 \pmod{4}$ , as the definition of Rabin's TDP

# Lesson 16

## 4.23 PKE schemes over DDH assumption

### 4.23.1 El Gamal scheme

Let's define a new  $\Pi = (\text{KGen}, \text{Enc}, \text{Dec})$ . Generate the needed (**public**) parameters  $(G, g, q) \leftarrow \text{GroupGen}(1^\lambda)^6$ .

The KeyGen algorithm is defined as follows:

- Pick  $x \leftarrow \mathbb{Z}_q$
- Output the key pair  $(pk, sk)$  as  $(g^x, x)$

The encryption routine  $\text{Enc}(pk, m)$  will:

- Pick  $r \leftarrow \mathbb{Z}_q$
- Output  $c = (c_1, c_2) = (g^r, pk^r \cdot m)^7$

The decryption routine  $\text{Dec}(sk, c)$  will:

- Compute  $\hat{m} = c_1^{-sk} \cdot c_2$

Correctness of this scheme follows from some algebraic steps:

$$\begin{aligned}\hat{m} &= \text{Dec}(sk, \text{Enc}(pk, m)) \\ &= \text{Dec}(x, \text{Enc}(g^x, m)) \\ &= \text{Dec}(x, (g^r, (g^x)^r \cdot m)) \\ &= (g^r)^{-x} \cdot (g^x)^r \cdot m \\ &= m\end{aligned}$$

**Theorem 28.** *Assuming DDH, the El Gamal scheme is CPA-secure.*  $\diamond$

*Proof.* Consider the two following games  $H_0(\lambda, b)$  and  $H_1(\lambda, b)$  defined as follows. Observe that  $b$  can be fixed without loss of generality.

---

<sup>6</sup>G could be any "valid" group such as  $\mathbb{QR}_p$  or an Elliptic Curve

<sup>7</sup>We need  $r$  because we want to re-randomize  $c$

$H_0(\lambda, b) :$

$H_1(\lambda, b) :$

**Note:** it is important to note that we can measure the advantage of  $\mathcal{A}$ , so fixed its output  $Adv_{\mathcal{A}}(\lambda) = \left| \underbrace{Pr[\mathcal{A} \rightarrow 1 \mid b=0]}_{\text{"}\mathcal{A} \text{ loses" }} - \underbrace{Pr[\mathcal{A} \rightarrow 1 \mid b=1]}_{\text{"}\mathcal{A} \text{ wins" }} \right|$ . Since  $b$  is fixed the above formula will give a value  $\lambda$  *innegl*, generally the advantage of an adversary is:  $\frac{1}{2} + \lambda$  (random guessing + a negligible factor).

Proof technique:  $H_0(\lambda, 0) \approx_c H_0(\lambda, 1) \equiv H_1(\lambda, 0) \approx_c H_1(\lambda, 1)$

$$\implies H_0(\lambda, 0) \approx_c H_1(\lambda, 1)$$

**Lemma 20.**  $\forall b \in \{0, 1\}, H_0(\lambda, 0) \approx_c H_0(\lambda, 1)$

*Fix  $b$ . (Reduction to DDH)*

Assume  $\exists$  PPT  $\mathcal{D}$  which is able to distinguish  $H_0(\lambda, b)$  and  $H_1(\lambda, b)$  with non negl. probability.  $\diamond$

*Proof.* Consider the following Game:

**Contradiction:**  $\mathcal{D}$  should be able to compute  $\log_g$  to distinguish the message.  $\square$

**Lemma 21.**  $H_1(\lambda, 0) \equiv H_1(\lambda, 1)$   $\diamond$

*Proof.* This follows from the fact that:  $(g^x, (g^r, g^z m_0)) \equiv (g^x, (g^r, U_\lambda) \equiv (g^x, (g^r, g^z m_1))$   $\square$

**Lemma 22.**  $H_1(\lambda, 1) \equiv H_0(\lambda, 1)$   $\diamond$

This is proved in the exact same way as **Lemma 20**. As a matter of fact it is the second part of the proof (where  $b$  is fixed to 1).  $\square$

### Properties of El Gamal PKE scheme

Some useful observations can be made about this scheme:

- It is **homomorphic**: Given two ciphertexts  $(c_1, c_2)$  and  $(c'_1, c'_2)$ , then doing the product between them yields another valid ciphertext:

$$\begin{aligned}
 & (c_1 \cdot c'_1, c_2 \cdot c'_2) \\
 &= (g^{r+r'}, h^{r+r'}(m \cdot m'))
 \end{aligned}$$

thus, decrypting  $c \cdot c'$ , gives  $m \cdot m'$ .

- It is **re-randomizable**: Given a ciphertext  $(c_1, c_2)$ , and  $r' \leftarrow^* \mathbb{Z}_q$ , then computing  $(g^{r'} \cdot c_1, h^{r'} \cdot c_2)$  results in a “fresh” encryption for the same message: the random value used at the encryption step will change from the original  $r$  to  $r + r'$

These properties of the El Gamal scheme can be desirable in some use cases, where a message must be kept secret to the second party. In fact, there are some PKE schemes which are designed to be **fully homomorphic**, i.e. they are homomorphic for any kind of function.

Consider the following use case: a client  $C$  has an object  $x$  and wants to apply a function  $f$  over it, but it lacks the computational power to execute it. There is another subject  $S$ , which is able to efficiently compute  $f$ , so the goal is to let it compute  $f(x)$  but the client wishes to keep  $x$  secret from him. This can be achieved using a FH-PKE scheme as follows:

Figure 4.35: Delegated secret computation

However one important consideration must be made: All these useful characteristics expose an inherent malleability of any fully homomorphic scheme: any attacker can manipulate ciphertexts efficiently, and with some predictable results. This compromises even CPA security of such schemes.

#### 4.23.2 Cramer-Shoup PKE scheme

This scheme is based on the standard DDH assumption, and has the advantage of being CCA secure. A powerful tool, called **Designated Verifier Non-Interactive Zero-Knowledge**, or alternatively **Hash-Proof System**, is used here.

##### Proof systems

Let  $L$  be a Turing-recognizable language in  $NP$ , and a predicate  $\mathcal{R} \in X \times Y \rightarrow \{0, 1\}$  such that:

$$L := \{y \in Y : \exists x \in X \mathcal{R}(x, y) = 1\}$$

where  $x$  is called a “witness” of  $y$ .

In our instance, let  $y = pq, x = (p, q)$

$\Pi = (\text{Setup}, \text{Prove}, \text{Verify})$

$(\omega, \tau) \leftarrow \text{Setup}(1^\lambda)$ , where  $\omega$  is the **Common Reference String**, and  $\tau$  is the **trapdoor**.

Additional notes:

- $\omega$  is public ( $= pk$ )
- $\tau$  is part of the secret key

- $\tau = (x, y) : \mathcal{R}(x, y) = 1$
- There is presumably a common third-party, which samples from the setup and publishes  $\omega$ , while giving  $\tau$  to only B.

T0D0 5: B operations in the image

Figure 4.36: Overview of Cramer-Shoup operation

Proof system - purpose: a way to convince  $B$  that  $A$  knows something  
 Can compute the proof in two different ways, this is the core notion of  $ZK$   
 No  $\tau \implies ZK$

### Properties

- (*implicit, against malicious Bob*) **Zero-knowledge**: Proof for  $x$  can be simulated without knowing  $x$  itself
- (*stronger, against malicious ALice*) **Soundness**: It is hard to produce a valid proof for any  $y \notin L$
- *honest people* **Completeness**:  $\forall y \in L, \forall (\omega, \tau) \leftarrow \text{Setup}(1^\lambda) :$   
 $\text{Prove}(\omega, x, y) = \text{Verify}(\tau, y)$

T0D0 6: to review and understand/better

### t-universality

**Definition 9.** Let  $\Pi$  be DV-NIKZ<sup>8</sup>.

We say it is *t-universal* if for any distinct

$$y_1, \dots, y_t \text{ s.t. } y_i \notin L (\forall i \in [t])$$

we have

$$(\omega, \text{Ver}(\tau, y_1), \dots, \text{Ver}(\tau, y_t)) = (\omega, v_1, \dots, v_t)$$

where  $(\omega, \tau) \leftarrow \text{Setup}(1^\lambda)$  and  $v_1, \dots, v_t \leftarrow \mathcal{P}$  where  $\mathcal{P}$  should be the proofs' space.  $\diamond$

<sup>8</sup>Designated verifier non-interactive zero-knowledge

### Enriching DV-NIKZ

Can we enrich DV-NIKZ with labels  $l \in \{0, 1\}^*$ ?

Suppose to have the following:

$$L' = L \parallel \{0, 1\}^* = \{(y, l) : y \in L \wedge l \in \{0, 1\}^*\}$$

Then our scheme changes :  $Prove(\omega, (y, l), x) = \Pi; Ver(\tau, (y, l))$  and , for  $t$ -*universality* , now we can consider 2 distinct  $(y_i, l_i)$ .

### Membership Hard Language (MH)

**Definition 10.** Language  $L$  is **MH** if  $\exists \bar{L}$  such that:

1.  $L \cap \bar{L} = \emptyset$
2.  $\exists$  PPT  $Samp$  outputting  $y \leftarrow \$\mathcal{Y}$  together with  $x \in \bar{\mathcal{X}}$  such that

$$R(y, x) = 1$$

(it's possible to say that  $Samp(1^\lambda) \leftarrow \$\mathcal{Y}$ )

3.  $\exists$  PPT  $\bar{Samp}$  outputting  $y \leftarrow \$\bar{L}$
4.  $\{y : (y, x) \leftarrow \$Samp(1^\lambda)\} \approx_c \{y : y \leftarrow \$\bar{Samp}(1^\lambda)\}$

◇

# Lesson 17

## 4.24 Construction of a CCA-secure PKE

This section exposes a construction of a CCA-secure PKE scheme, using hash-proof systems, membership-hardness, and the  $n$ -universality property.

Let  $\Pi_1, \Pi_2$  be two distinct hash-proof systems for some NP language  $L$  and the range of  $Prove_2$  supports labels ( $L' = L || \{0, 1\}^\ell$ ).

Construct the CCA scheme as follows:  $\Pi := (\mathcal{KGen}, Enc, Dec)$

- $(\overbrace{(\omega_1, \omega_2)}^{pk}, \overbrace{(\tau_1, \tau_2)}^{sk}) \leftarrow^* \mathcal{KGen}(1^\lambda)$  ,  $(\omega_1, \tau_1) \leftarrow^* Setup_1(1^\lambda), (\omega_2, \tau_2) \leftarrow^* Setup_2(1^\lambda)$
- Encryption routine:  $Enc((\omega_1, \omega_2), m)$ 
  - $(y, x) \leftarrow^* Sample_1(1^\lambda)$
  - $\pi_1 \leftarrow^* Prove_1(\omega_1, y, x)$
  - $l := \pi_1 \cdot m$
  - $\pi_2 \leftarrow^* Prove_2(\omega_2, (y, l), x)$
  - $c := (c_1, c_2) = ((y, l), \pi_2)$
- Decryption routine:  $Dec((\tau_1, \tau_2), (c_1, c_2))$ 
  - $\hat{\pi}_2 = Verify_2(\tau_2, c_1)$
  - IF  $\hat{\pi}_2 \neq c_2$  THEN OUTPUT FALSE
  - Recall:  $c_1 = (y, l)$
  - $\hat{\pi}_1 = Verify_1(\tau_1, y)$
  - OUTPUT  $l \cdot \hat{\pi}_1^{-1}$

Correctness (assume  $\hat{\pi}_i = \pi_i \forall i$ ):

$$\begin{aligned}
 \hat{m} &= Dec(sk, Enc(pk, m)) \\
 &= Dec((\tau_1, \tau_2), Enc((\omega_1, \omega_2), m)) \\
 &= Dec((\tau_1, \tau_2), ((y, l), \pi_2)) \\
 &= l \cdot \hat{\pi}_1^{-1} \\
 &= \pi_1 \cdot m \cdot \hat{\pi}_1^{-1} \\
 &= m
 \end{aligned}$$

Some additional notes (may be incorrect):

- The message space of the second prover is the range of the first prover.
- The message space of the first prover is a multiplicative group
- The message space of the second prover is a polylogarithmic language in  $(\lambda)$

Theorem: Assuming  $\pi_1$  is 1-universal,  $\pi_2$  is 2-universal and  $L$  is Membership-hard, then the above scheme is CCA-secure.

Proof: Five different games will be defined:

T0D0 7: "I diagrammi arriveranno con un ritardo che preciserò al più presto.  
Mi scuso per il disagio."  
- Trenitalia style

REVIEW: referencing something from another part of lesson 17

#### 4.24.1 Instantiation of U-HPS (Universal Hash Proof System)

$\exists r$  using a DDH language such that  $L_{DDH} = \{(c_1, c_2), \exists r | c_1 = g_1^r, c_2 = g_2^r\}$

Given a group  $\mathcal{G}$  of order  $q$  with  $(g_1, g_2)$  as generators:

$$G_2 = g^x, g_1 = g, r = g$$

$$(g, g^x, g^y, g^{xy})$$

Now we can define our U-HPS  $\Pi := (\text{Setup}, \text{Prove}, \text{Verify})$

- *Setup*( $1^\lambda$ ): Pick  $x_1, x_2 \leftarrow \mathbb{Z}_q$  and define:  
 $\omega = h_1 = g_1^{x_1} g_2^{x_2}$ ,  $\tau = (x_1, x_2)$
- *Prove*( $\omega, \underbrace{(c_1, c_2)}_y, r$ ) output  $\Pi = \omega^2$
- *Verify*( $\tau, \underbrace{(c_1, c_2)}_y$ ) output  $\tilde{\Pi} = c_1^{x_1} c_2^{x_2}$

**Correctness:**  $\Pi = \omega^2 = (g_1^{x_1} g_2^{x_2})^r = g_1^{rx_1} g_2^{rx_2} = c_1^{x_1} c_2^{x_2} = \tilde{\Pi}$

**Theorem 29.** If  $(c_1, c_2) \notin L_{DDH}$  the distribution  $(\omega = h_1, \tilde{\Pi} = \text{Verify}(\tau, (c_1, c_2)))$  is indistinguishable from a truly random string.  $\diamond$

*Proof.* Define a **MAP**  $\mu(\overbrace{x_1, x_2}^{\text{random}}) = (\omega, \Pi) = (g_1^{x_1} g_2^{x_2}, c_1^{x_1} c_2^{x_2})$  it suffices to prove that  $\mu$  is injective. This can easily be done with some constraints:  $\mu'(x_1, x_2) = \log_{g_1}(\mu(x_1, x_2)) = (\log_{g_1}(\omega), \log_{g_1}(\Pi))$   
For  $r_1 \neq r_2$  then  $c_1 = g_1^{r_1}, c_2 = g_2^{r_2} = g^{\alpha r_2}$ . For  $\alpha = \log_{g_2} g_1$  then  $\Pi = c_1^{x_1} c_2^{x_2} = g_1^{r_1 x_1} g_2^{r_1 x_1 + \alpha r_2 x_2}$ .

$$\mu'(x_1, x_2) = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} = \begin{pmatrix} 1 & \alpha \\ r_1 & r_2 \alpha \end{pmatrix} \cdot \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

Since  $\text{Det} \begin{pmatrix} 1 & \alpha \\ r_1 & r_2 \alpha \end{pmatrix} = \alpha(r_2 - r_1) \neq 0$  the map is injective.

□
